Such a body could make a thorough study, to take one example, of the efficacy of probation, and the criteria for placing an offender on probation and for prescribing the actual form of probationary care. Dr. John Bowlby held that the new research should be planned on the assumptions that the extent to which any of us conform to social codes is a matter of degree; that those who violate social codes do so for various reasons and can be grouped accordingly; and that we must not confine our attention to those brought before the courts, but must study antisocial behaviour wherever it is found. This generous programme should ensure that any such research body will be kept occupied for the next few centuries; it could certainly contribute greatly to our present knowledge.

FLUORINE IN FOODS

The Ministry of Education's appointment of a Working Party[1] to investigate the prophylactic effect of locally applied fluorides has once more drawn attention to the dual rôle of fluorine in human nutrition.[2]

In early life the risk of dental caries is reduced by drinking water containing about one part per million (p.p.m.) of fluorine; but many communal water-supplies do not provide this amount. McClure[3] has shown that the urinary fluorine content is a valuable guide to the intake of fluorine. The average diet appears to yield about 0·2–0·3 mg. daily. Most foods contain 0·2–0·3 p.p.m. or less, but tea and sea-foods are notable exceptions; dry tea contains 75–100 p.p.m. and sea-foods 5–15 p.p.m. Cow's milk contains about 0·1–0·2 p.p.m.; and when the cow is fed with additional fluorine the content in the milk is not increased. Nor does the fluorine content of edible plants vary appreciably with differing concentrations of fluorine in the soil and water of the place where they are grown; the high figures occasionally reported for leafy vegetables have been related to atmospheric pollution from nearby industries.

In childhood the average diet does not yield enough fluorine to safeguard the teeth. Up to the age of 16 an additional 0·4–1·1 mg. of fluorine, according to age, should be assimilated each day beyond what is contained in the food and in drinking-water (on the assumption that the optimum fluorine content of drinking-water is 1 p.p.m.). A supplement to make good this deficiency may perhaps be justified.

PROFESSIONAL PROTECTION

> "Who steals my purse steals trash, . . . but he who filches from me my good name robs me of that which not enriches him and makes me poor indeed."

These apt words appear in the latest report of the Medical Protection Society. This report and that of the Medical Defence Union serve once more to remind members of the medical and dental professions of the need not only for unceasing professional vigilance but also for a strong organisation to come to their help promptly. However skilled he may be and however high his standard of conscientiousness and devotion to duty, a doctor or dentist remains at the mercy of the cantankerous, the deliberately difficult, and the malignant. We are but human and all of us make mistakes; moreover, in these days, a nodding acquaintance with medicine through the popular press sometimes leads the public to expect much more than we can perform. Having read about some "miracle cure," the person who does not progress as rapidly or as satisfactorily as he would wish is often inclined to blame the doctor rather than the drug. Now that everyone has a right to treatment under the National Health Service there is probably a greater tendency to complain. Complaints are made about the doctor's manners, or about his slowness in visiting the patient; or he is accused of examining less fully than the patient had expected or, alternatively, more fully than the patient had desired. Every complaint sent to an executive council must be investigated; the doctor must be asked for his observations; and sometimes there must be a hearing. Whether a hearing takes place or not, it is certain that the doctor needs at a moment's call the counsel of experts, and he needs at all times the sense that behind him are staunch and willing allies.

Happily the need is met—and very well met—by the medical defence societies. On Sept. 24 we reported the annual meeting of the Medical Defence Union (49, Bedford Square, London, W.C.1.), and this week we report the annual meeting of the Medical Protection Society (Victory House, Leicester Square, W.C.2) at which Sir Ernest Rock Carling gave some wise advice. For our own part we think it important that all reasonable complaints by patients should be aired, whether they are made against the service as a whole or against individuals. But even quite a small complaint can cause much trouble and distress to a doctor, and nowadays it is little short of folly to practise medicine of any kind without taking the obvious precaution.

SEDORMID AND THROMBOCYTOPENIC PURPURA

'Sedormid' (allyl-isopropyl acetyl urea) has long been known to cause thrombocytopenic purpura; the first case was described in 1933,[1] and of those reported in these columns the latest was published last year.[2] This complication is due to hypersensitivity, and once it is established even minute doses may produce purpura. Ackroyd[3] concludes from a study of 3 cases that in purpura due to this drug there is both a capillary defect and a fall in the platelet-count. He has found that *sedormid directly affects the platelet-count of in-vitro* blood from sensitive individuals but not from normal controls; in the sensitive it apparently leads to a specific agglutination of platelets. He has also shown, however, that in sensitive subjects sedormid applied as a patch test can *cause local hæmorrhages in the absence of general* increase in capillary fragility or of thrombocytopenia. As a measure of sensitivity the in-vitro test which he describes may prove a satisfactory alternative to the test dose, which is not always free from danger.

Thrombocytopenia due to drugs is uncommon; but sedormid ranks relatively high among the causes. Other drugs of the same group—the open-chain ureides—do not apparently have this effect.

WORLD MEDICAL ASSOCIATION

Twenty-four countries are to be represented at next week's meeting in London of the World Medical Association. This association, membership of which is open to national medical associations, was formed at a meeting in London three years ago[4] and has as its first aim the promotion of closer ties among the national medical organisations and among doctors. Dr. Charles Hill, secretary of the British Medical Association, will preside over next week's meeting which begins on Tuesday. It will have before it the reports of committees which have been studying social-security schemes, post-graduate education, the wording of an international code of medical ethics, the relation of the profession to the medical press, and the "standards of medical care and allied subjects"—including such matters as unqualified practice and the advertisement and sale of patent medicines.

AMERICAN HOSPITAL CONVENTION

FROM A CORRESPONDENT

FTER the fantasy of New York, Cleveland (Ohio) as almost sedate. In the early morning mist the impression was indeed rather one of Edinburgh. eland is an ideal city in which to hold a convention. hotels are large and comfortable, and there is a y impressive public auditorium.

he importance of the 51st annual convention of the erican Hospital Association is evident both from the iber and quality of those attending—and this con- tion is representative of all groups interested in the of the patient. The programme keeps a nice ince between discussion on future policy on the one d and the technicalities of hospital planning and inistration on the other.

he main preoccupation of hospitals at present is to ntain independence and at the same time secure financial assistance so necessary to meet rapidly rising ts. The problem was well put at the first general tion by Professor Dimock, a political scientist, who icated the extremes of State and voluntary control l suggested the middle way of coöperation. He was owed by a speaker on the hospital service which anised labour desires. Mrs. Eugene Meyer, of the *shington Post*, then spoke on what the public is ecting from hospitals, and it was interesting to note t she included a firm demand for more medical adminis- tors. Senator Lister Hill's announcement of recent islation to provide more Federal funds for hospital rposes was received with applause.

The next general session dealt with approaches to the tribution of hospital care. Government programmes re described by Dr. Mott, of Saskatchewan, Dr. Hershey, British Columbia, and Dr. A. L. Banks, of the British nistry of Health, and these contributions were cussed by a panel. The anxieties facing the hospital rld in the United States were again brought out. e traditional desire for independence was illustrated Father McGowan when he declared “ No government ould do for the people what the people can do for emselves ” and that “ those who roll up their sleeves dom ‘ lose their shirts.’ ” Mr. J. Douglas Colman phasised the benefits of the Blue Cross scheme, which w covers 61,000,000 people. It was clear that in the ckground is the fear of the Welfare State, and Dr. well Reed summarised the general opinion when he id that the United States has no need to hurry and at time for experimentation would be well spent.

It was interesting to feel the sympathy toward itain and the British experiment. To the observer seems clear that the eventual pattern in the United ates will take the form of substantial Federal grants ith a minimum of central control, allowing experiment individual States and Territories. The incalculable ctor is the operation of pressure groups which play ich a dominating part in the American politico-social onomy. The power and force of these pressure oups is startling to the newcomer.

The technical discussions, both formal and informal, re stimulating and depressing to an Englishman. edical men meet late at night and early in the morning he breakfast-discussion group is at first a rather trying henomenon). Their talk is not of terms and conditions f service but of the future, and they are full of optimism. rchitects show plans of dream hospitals which are ctually being built. The exhibition of course is a kind of hospital fairyland. One thing is quite clear. If we, n Great Britain, are to keep abreast of developments n the United States we must be prepared to send a onstant stream of young men there to study. This pplies particularly to business methods in hospital administration and finance.

MEDICAL PROTECTION SOCIETY

Sir ERNEST ROCK CARLING, presiding over the annual meeting on Sept. 28, said that applications to this society for assistance, of very varied kinds, now average more than forty a week. The society could assist members at hearings by medical and dental services committees, and would like to have the earliest possible information of any charges made. Members should obtain the secretary's help before answering any letter on this subject from the clerk of the executive council.

Year by year, continued Sir Ernest, the society had exhorted practitioners not to omit radiography in any case of injury where negligence might later be alleged. It had lately been suggested that the shortage of films and the pressure on radiological departments were such that this precaution should be discontinued and the public should be educated to understand that films were sometimes unnecessary. But it was the legal profession, not the public, that needed educating in this matter, judging by the terms of their accusations against doctors, and he earnestly hoped that members would continue to take X-ray photographs whenever the occasion suggested it.

Speaking of the constant need for care, Sir Ernest referred particularly to intravenous fluids and the risk of injecting thiopentone into the tissues, to the damage done not only by applying plaster-of-paris too tightly but also in removing plaster or even adhesive dressings unskilfully; and to the perennial question of swabs left in the abdomen and elsewhere. The time has come, he thought, for an inquiry by some authoritative body, into the best methods of controlling swabs. Also cases still arose in which teeth were knocked out by gags, and the responsibility for putting the gag in position and keeping it there ought to be clearly placed on one person—either the surgeon or the anæsthetist. Finally, when needles were broken, the parts should be kept for examination by a metallurgist: in all those sent by the society for examination a defect had been found.

Mr. W. M. MOLLISON said that in the past year the expenses per member had exceeded the annual subscription of £1; but, with reserves at £112,407 the council did not feel that the deficit justified an increase in the subscription.

The annual report shows that almost 1800 new members were elected during 1948, and that the total income was £26,662. The excess of expenditure over income (£1528) was partly offset by a profit on the sale of investments, and the accumulated funds were reduced by only £583. The society's financial resources at the end of the year were estimated at £146,814. In addition it is reinsured with Lloyd's underwriters in respect of any sum above about £10,325 which it may have to pay by way of adverse costs and damages in any one year. The report contains information and advice on the legal problems of sterilisation, certificates, evidence in court, and fees to witnesses, and also summaries of illuminating cases. It points out that “ an assistant may seem less liable than a principal in that he works under the direction of the latter, but he is certainly not immune from legal actions arising out of his professional work. *Any* practitioner is in law responsible for his professional acts and omissions and the fact that a principal can be sued on account of the acts of his assistant in no way decreases the assistant's responsibility. A locum tenens, on the other hand, does not work under supervision. He replaces the practitioner for whom he is acting. Nevertheless, members are advised before engaging any locum tenens to satisfy themselves as to his credentials, as a practitioner must take reasonable care to ensure that his deputy is a registered practitioner. . . . Under the National Health Service Regulations a practitioner is responsible for all acts or omissions of any practitioner acting as his deputy or assistant in relation to his obligations under the terms of service.”

Sir Ernest Rock Carling was re-elected president, Mr. W. M. Mollison treasurer, and Dr. A. R. French secretary.

the bedside is not disease, but disease in a patient. When you are asked to stitch up a cut finger it may not seem to matter very much what *type of personality* the patient has; though it is rather fun to try and find out without taking too much time about it. But if the patient has broken his leg, or has to undergo any long illness, his subsequent successful return to his work, and his happiness at home, will largely depend on what type of man he is, and the particular measures which are taken to deal with his reactions to illness. Of the people who are suddenly removed from their normal life by breaking a leg, some may be perfectly philosophical and sensible, with assured jobs to which they promptly return when the leg is mended; but others may be so constituted or circumstanced that they are *consumed by genuine or imagined worries which will* produce strange symptoms—symptoms which are not in the textbooks. And if not treated these symptoms will interfere with the patient's return to normal life.

The study of your patients' personality is not a matter for the psychiatrists: it can be formulated on systematic common-sense lines and it is something which all doctors can do themselves. And it can be learned by the medical student. What it amounts to in essence is that in addition to studying the patient's disease you find out about his life and work and family background. If you are prepared to give the time to listening to what he has to tell you of himself, you will be richly rewarded, not only by rapidly acquiring a knowledge of human nature but also by increasing your effectiveness in treatment. And the patient will have much more confidence in you than if you merely regard him as a case.

MEDICINE AND THE SCIENCES

So far I have talked about the art of medicine and now I must say something about the science, and its relations with the other sciences. It must already be clear to you that progress in clinical medicine is largely dependent on advances in the basic and biological sciences. In my student days, when we passed our examinations in physics and chemistry and even in the preclinical subjects, we often said to ourselves: "Thank *goodness that's over and done with.*" This was a short-sighted policy, and with each new application of science to medicine—such subjects as electronics, modern statistical methods, radioactive isotopes, and the application of plastics in surgery and dentistry—I find myself regretting my lack of basic scientific knowledge.

No-one can hope to keep up with more than a fraction of the research work going on, but, such is the pace and power of scientific progress that it is essential for your competence and your intellectual comfort as doctors that you should maintain a general interest in scientific matters. This sounds a tall order, but it is surprising how much you can glean from the popular scientific journals and from talking to your scientific friends. Never forget how very much in medical science is still unknown. Beyond the established knowledge set out in your textbooks there are many things which will be discovered in your lifetime, often with profound influence on your medical practice.

What part can the clinician himself play in research? There is scarcely a disease in which a thorough and sustained clinical investigation will not add new facts, and occasionally discoveries of outstanding importance can be made by clinicians who keep good records and are alert to observe the unusual. A recent example is the discovery by Gregg, an Australian ophthalmologist, that german measles in the early months of pregnancy may seriously damage the organs of sight or hearing of the fœtus. The application of scientific discoveries in the clinical field—for example, the application of new remedies—also requires careful clinical research; and the whole clinical field is full of problems which can be *worked out by a combined attack* in the wards and laboratories.

One must be prepared to approach one's clinical problems on the broadest possible basis. In the last *50 years with the growth of specialisation there has been* a dangerous narrowing of medical activities. I can best illustrate this trend by reminding you that Lister was appointed professor of surgery at this hospital his inaugural lecture was mainly on the fermentation of milk. What would people think today if a professor of surgery gave a lecture about milk? They would say that he was neglecting surgery and encroaching on the field of the bacteriologist or hygienist. But to Lister it was a perfectly natural thing to do. Bacteriology was a young subject to which surgeons as well *as others were making important contributions.* Lister owed his discovery of antiseptics to two things: first to his thorough and persistent study, at the bedside and in the laboratory, of the healing of wounds; and secondly, *to his broad approach to the problem.* When his colleague Thomas Anderson, the professor of chemistry at Glasgow, said to him one day: "By the way, have you read the papers of a French chemist, Pasteur, on fermentation?" Lister read these papers and with his prepared mind at once realised that it might be the living germs described by Pasteur and not the oxygen of the air which caused wounds to putrefy. And so began his use of carbolic acid. In the lecture on milk Lister was proving again for the sceptics that there was no such thing as spontaneous generation and that *the bacteria in the wound came in from the air.* This principle was essential for his antiseptic system. And also in this work with the *Bacterium lactis* Lister developed a successful technique for obtaining a pure culture of a bacterium, and this was the first time it had been done. Thus Lister approached his problem not only as a practising surgeon but also as a pathologist, as a bacteriologist, and as an experimenter; and, as I have advised you to do, he cultivated his scientific friends. The chemist Thomas Anderson, I have been told, not only drew Lister's attention to Pasteur's papers but also told him about carbolic acid as a possible disinfectant.

CONCLUSION

You may be thinking that I have been holding out to you ideals which are impossible of attainment. I have been urging you to become good doctors, to keep up with scientific progress, and to undertake research. *How can one man do all these things?* The answer is that no-one can excel in all fields. You will evolve in different ways. Most of you should become good doctors; some will take readily to research, while others —and they will include many *good doctors*—will have no aptitude for it. But I do think that nearly every young doctor should try his hand at one investigation—should try to carry knowledge of some disease or symptom or function, or the effect of *some form of* treatment a stage further than it has been carried before. Otherwise he will not find out what he is good for, nor will he appreciate the difficulties and labours involved in discovering new things.

I have not said anything about material objectives—careers, salaries, and so on. In medicine direct pursuit of *these not unimportant* aspects of life is apt to prove disappointing, and the greatest personal success is usually incidental to a life spent in service to patients or in research. That is one of the dignities of our profession. *We are still, I am thankful* to say, a guild; and in the course of your careers you will receive much help from your seniors which you cannot hope to repay, except by passing it on to the next generation.

Parliament

Value of Our Social Services

the House of Lords on Sept. 27, in opening the te on the exchange value of the pound, Lord son reaffirmed the Government's determination to intain those services for the children, the aged, the and the unfortunate for which this country is the er among the nations." Other Noble Lords, how- found themselves unable to be equally reassuring.

unt Samuel said that many of the measures lately ed had been advocated by the Liberal party for y years. The new National Health Service was lutely right in principle. The old inadequate service a disgrace to the country, and there was an insuffi- y of hospital accommodation, maintained only by ing around for voluntary subscriptions. But the of the National Health Service had proved to be far ter than even its authors expected and it now lved a charge of £260 million. National Insurance, onal Assistance, and family allowances cost a further million. Not only were these services costly icially, but they were also costly industrially, their administration withdrew from productive loyment many thousands of people. The present ernment, he continued, might say "We shall never the social services: they must be maintained at all s." But they might raise the price of grain and of t, and in a family with a number of children this ld have the same effects as if allowances were cut, by one shilling a child.

ord Balfour of Burleigh pointed out that Lord eridge had postulated 3% temporary unemployment. present percentage was $1^1/_2$%, which meant that 250,000 people were unemployed out of the working ulation of 20 million. He submitted that this over- employment was hindering the redistribution of our our force to essential industries. He hoped he would acquitted of lack of sympathy either with social ism or with continuing unemployment, but he felt t we must have retrenchment and reform if we were get out of our troubles. We had reached the point en we could not pay for all the desirable objectives wanted. We must choose between the more essential l the less essential, and he did not think it fair of the ernment to dodge that issue. It was common und that there was waste in the health service which st be eliminated, but he would go further. People, suggested, did not appreciate a thing when they ught someone else was paying. He advocated the position of a token charge for services received under great health schemes with, he would at once add, eguards for the indigent.

iscount Bruce of Melbourne deplored the Govern- nt's apparent suggestion that devaluation was an ernative to unemployment and cutting down the ial services. The Chancellor should have told the ople that devaluation was the only trump left in his nd, and that if it failed to take the trick there was no ernative to unemployment, a lowering of the ndard of living, and a reduction of our social services. rd Bruce urged that we should immediately frame a o-year emergency programme—including reduction in penditure on the social services—which should be bmitted for endorsement at an early General Election.

Opening the second day of the debate, Viscount witt, the Lord Chancellor, affirmed that sickness and health caused the greatest waste of all in this country. oper safeguard of the health of the people made for ficiency. It would be wrong to interfere with the ope of these services though he agreed we should try get rid of all waste and extravagance which may lie thin them. On a division the Opposition's amendment as carried by 93 to 24.

The Chancellor's Views

Sir Stafford Cripps, who opened the debate in the House of Commons, called upon the people for full operation with the Government in achieving their nancial and trade aims while maintaining full employment and safeguarding the social services. The Government, he said, were under no illusion as to the gravity of the decision they had taken, nor did they underestimate the effect it would have upon the life and livelihood of the people. They also appreciated that devaluation was bound to have an impact upon practically every other national economy throughout the world.

Dealing with the measures which it would be necessary to take to deal with the situation, Sir Stafford Cripps said our internal expenditure must be limited. We must not allow our desire to have more than we could afford to endanger our present standards, as it would do unless we reduced the inflationary pressure which was again present in our economy and which the new circumstances might intensify. The two domestic uses of the goods and services we produced or imported which competed with the consumers' market were capital investment and Government expenditure. We must look to both of these to provide some easement of inflationary pressure. The Government were not prepared to reduce the scope of the social services provided for the people. But they must economise to the utmost and avoid all waste in those services just as in others. Because they meant to continue those services it did not mean that no economies could be made.

Mr. Oliver Stanley contended that it was both dishonest and dangerous to say that there was a choice between two policies—one of mass unemployment and the lowering of the social services, and the other, which the Government had adopted, which would safeguard both these things. No-one would pretend that the expedient which the Government had adopted did anything to safeguard full employment or the social services. On the contrary, it increased the risk of both.

On the second day, Mr. Winston Churchill moved an Opposition amendment welcoming the financial and economic measures agreed upon in Washington, but regretting that the Government, as a result of four years of financial mismanagement, had now been brought to a drastic devaluation of the pound sterling. The motion also expressed the view that a return to national prosperity, the maintenance of full employment, and the safeguarding of the social services, could never be assured under the present administration. In concluding his speech, Mr. Churchill said there was no reason why the struggle of the masses for a more spacious life, for shorter hours, for constantly improving conditions of labour should not be crowned with increasing success provided that mistaken guides did not enforce the rule that all must come to the table at once or none at all.

Mr. Clement Davies intimated that the Liberal party could not support the Government motion. He said that no-one wanted to cut welfare, national insurance, and so on, but would not the Government realise that through the food subsidies they subsidised incomes that did not need it? They should increase the grants to the lower-income groups and increase family allowances. Mr. Quintin Hogg pointed out that the devaluation of the pound meant that every social service in the country had been cut. The poorest in the community would be hit the hardest. The Minister of Health was jeopardising the future of the National Health Service by riotous and extravagant administration. That administration had pursued a corrupt and demoralising progress and there was no effective machinery by which the public money and interest could be safeguarded. He would be surprised if the Chancellor survived to another Budget and did not institute some reform in that service.

Summing Up

Mr. Aneurin Bevan, the Minister of Health, opened the third day's debate with a vigorous fighting speech. He reminded the Opposition that the last favourable balance of payments which this country had enjoyed was in 1935. In the years 1936, 1937, and 1938 the average number of unemployed was 2 million. If those people had been at work consuming imported foods and raw materials there would have been a catastrophic financial crisis. The present Government came into office in 1945, and by the last half of 1948 the country showed a favourable balance (of £30 million) for the first time since 1935. That excluded Marshall aid. The

Disabilities

40. ESSENTIAL HYPERTENSION

As a disability for females I can thoroughly recommend mine. It has every modern advantage over the vapours, the greensickness, and the decline, while retaining all their more agreeable features. I suppose I have had it —or the tendency to it—most of my life, for when, as students, we all had our blood-pressures taken for some piece of research or other, I was always 140/100 while my contemporaries were an orthodox 120/90. At the time I put it down to anxiety about examinations; we were great on anxiety in my family. I grew from a thin active anxious little girl to a stout anxious depressed adolescent, and then to a plumpish maturity in which moods of gaiety and depression fluctuated. But as the years went by and (as I suppose) my blood-pressure rose, I became *more uniformly cheerful*; and now at forty-eight I suspect my almost continuous euphoria of being a symptom of my state.

The diagnosis of hypertension was made quite by chance five years ago. I had gone to my doctor about some bleeding from my bowel, which I supposed to be due to piles. But I had no piles, and I had had several hæmorrhages under the skin in various parts of my body; she said I had purpura and must see a consultant. Then she casually took my blood-pressure and shocked us both (she was an old friend) by finding it was 240/120. I felt quite well, and said so rather crossly; but when we came to look at my story more critically this didn't seem quite true; for I had been getting more and more breathless in my Sunday climbs about the hills, and my ankles had been swelling a bit, and in bed at night my heart-beat thundered in my ears. So I saw a consultant, who said that there it was, I had essential hypertension, and that I would live the sort of life that people with hypertension live, probably feeling splendid, and that in the end I should die as hypertensives die, probably from a stroke, and who could ask anything better? I agreed warmly with every word he said, and decided to take no further notice of my blood-pressure as long as it caused me no annoyance. He looked into the purpura carefully, and that turned out to be obscure but irrelevant: if I had been in my 'teens they would have called it Henoch's purpura; as it is they keep silent.

The next thing that happened, about a year later, was a hæmorrhage into my retina—a tiny one, but enough to blur central vision and to send me back to my consultant in a great state of excitement. He was superbly reassuring. It was a purpuric hæmorrhage, he said, nothing to do with the hypertension, and it would clear up, leaving very little disability. As usual, he was perfectly right: that is exactly what has happened. All the same, he sent me to bed for a month, and told me I must take life more easily. He was not unreasonable in that, for I have a weakness for complicating my life; and at that time I was doing a full-time job, travelling up to it daily from the country, keeping house for two partial invalids, doing a good deal of the cooking, making most of my own clothes, and producing plays whenever I got the opportunity. It does seem rather a full programme, looking back, but it didn't seem anything special at the time. That is the great charm of hypertension: one goes at things like steam. An operation—also irrelevant to the main story—retarded my return to work, and when I was taken on again it was as a part-timer: so for the rest of the week I now put my feet up.

But of course there are more ways of being active than by climbing the Matterhorn; and as it happens I have always been rather lazy physically, so I take kindly to this Elizabeth Barrett Browning life: or I would if we always had a char. I still do some of the cooking, which I like; but I live nearer my work, and thanks to the conviction of my doctor that I need it I get petrol to take me there. I don't make as many clothes as I did, and I haven't produced any plays for longer than agrees with me; but I have managed to fill up my time in other ways—by writing and lecturing and so on. I can't pretend, even to my consultant, who always incites me to idleness, that I don't work full-time; but it is in my own time, and largely in my own home, which I find congenial.

The reward of this relative virtue is that my condition has remained stationary, and even improved slightly in the last five years. My last blood-pressure reading (it gets done about once a year with luck) was 220/1 The purpura reappears occasionally and does its st but it has kept out of my retinæ, which is good enough for me. I sleep well, I eat rather too well, I very rarely (about once a year) get a headache. My heart-beats have ceased to pound in my ears when I put my head on the pillow; I can't think why, on the evidence. Perhaps this is a purely psychosomatic symptom. I can get tired when I do too much physically, notably if I go rushing round London in buses and trains; but who doesn't? This summer I swam and played gentle tennis and felt all the better for it, though my family watched my first dive with the air of people about to hear a loud explosion. Incidentally, kindly concern can go too far; it is no pleasure to the subject to be treated as though his next act will be his last. Relatives should try to live and let live.

"Suppose we had done a sympathectomy on you five years ago," my consultant said, at my last visit, "how pleased we should be with the result." Suppose I had gone on doing just what I was doing, I couldn't help thinking, should we perhaps be equally pleased? Are *some* people wound up to go at my pace, just as some cars do better with the engine running faster? I put the thought politely into words. "Why," I asked, "am I not as good as the next woman?" "In some ways," he replied (but after a pause), "you are, as you know, better." By which I suspect he meant that it *pays me to go quietly*.

He went on to tell me that on the whole women take essential hypertension—and indeed all kinds of hypertension—better than men; that he had had women like me coming up to his outpatients with little change for twenty years. It seems there is no known explanation for this difference, so I shall put *it* down to the Y chromosome.

Well there it is: I offer the suggestion to any woman who would like to be urged to rest and let someone else do it, to be treated with tenderness and concern by her family, to put her feet up for several hours a day, to be encouraged to go by car or take a taxi, and yet to feel brimming with health and energy, and to last for years with the hope of a quick finish at the end of it. Essential hypertension is the name.

Medicine and the Law

A Further Death From Hepatitis

LAST week (p. 630) we described the investigation, by the St. Pancras coroner, of the death of three children who developed hepatitis after serum had been injected for the purpose of protecting them against measles. On the same day the same coroner inquired into the death of a 66-year-old woman who, after operation in hospital, received blood-transfusion. According to the *Manchester Guardian* (Sept. 27), a pathologist reported that the case was comparable with those of the children except that in the children death followed the injection of serum. The coroner, returning a verdict of death by misadventure, remarked that the accident was very rare and was no argument against blood-transfusion.

Poliomyelitis

ring the week ended Sept. 24, notifications in and and Wales numbered: poliomyelitis 268 (311), encephalitis 27 (31). The figures for the previous are shown in parentheses. This is the first substan- fall since the rise in notifications began in the ty-fourth week of this year. The curve generally followed that of 1947 fairly closely and it is to be d that the decline, which began that year in the week d Sept. 13, has now set in.

ltiple cases (poliomyelitis and polioencephalitis ther) were reported from the following counties: lon 48 (41), Berkshire 3 (7), Chester 7 (4), Cornwall), *Devon 5 (5), Dorset 4 (3), Essex 17 (18), Hertford*), Kent 18 (16), Lancaster 24 (29), Leicester 5 (13), s, Holland 4 (1), Lincs, Lindsey 4 (6), Middlesex 20 Norfolk 2 (3), Northampton 4 (3), Northumberland 10), Nottingham 9 (11), Oxford 3 (0), Peterborough, of 2 (1), Somerset 7 (8), Southampton 8 (10), lk, East 5 (1), Surrey 11 (14), Sussex, West 2 (1), wick 8 (10), Westmorland 2 (0), Wiltshire 9 (6), s, West Riding 19 (33), Glamorgan 3 (3).

The Changing Population

report [1] issued this week by the Registrar-General s the civilian populations of each local-government in England and Wales, including the numbers of sex at various age-groups. The report also serves raw attention once again to the changing age- ibution of the population. At Dec. 31, 1947, the to which the report refers, the distribution for the le country was as follows:

e, rs	*% of total*	*Age, years*	*% of total*	*Age, years*	*% of total*
	8·5	35–	8·1	70–	3·2
	6·8	40–	7·8	75–	2·0
	6·6	45–	7·1	80–	1·0
	6·0	50–	6·2	85 and over	0 5
	6·3	55–	5·6		
	7·6	60–	5·0		
	7·5	65–	4·2		100·0

e the 1931 census the proportion of the population er 15 years of age has fallen from 23·8% to 21·9%, the proportion over 65 has risen from 7·4% to 10·9%. percentages for selected years since 1911 are as ows:

Age, years	*% of total population* 1911*	1921*	1931	1939*	1947
nder 15	30	30	24	21	22
5 and over	5	5	7	9	11

rived from figures given in the Registrar-General's annual reports.

he report reveals the following ratio of males to ry 1000 females:

ages	18–19	20–24	25–34	35–44	45–54
40	1017	1021	986	992	988

In England Now

A Running Commentary by Peripatetic Correspondents

ONE of my ex-H.P.S, in writing to me for a testimonial to support his application for an appointment, subscribed himself, "Yours ever, Mick." Now in my day I should no more have assumed this familiarity towards a chief than (when in the uniform of a temporary lieutenant, R.A.M.C), I should have thought of clapping the D.G. on the shoulder with an inquiry as to his well-being. And so, whilst responding to "Mick's" request with a certificate which described him as a sort of composite of the Three Wise Men of the East and the Nine Muses, I pondered the reason for this changed relationship.

In bygone days the chief had an aloofness compounded partly of admiration and reverence, partly of fear. In lesser degree perhaps, this sentiment applied to the domestic circle: we called our father, "Sir"—a title now rarely, if ever, heard in the home. Have we lost or gained by the substitution of affection for respect? Herein at least may lie an explanation for the disappearance of "characters" or "personalities" who acquired their reputation by acts of violence, fits of temper, and other unpleasantnesses for which they seem to be perpetuated in memory by appropriate anecdotes. Yet possibly even we apparent milksops of today are establishing ourselves as personalities by some eccentricity or quiddity of which we are unaware.

* * *

The enforced idleness of what used to be called lumbago and nowadays gallivants as a prolapsed disc has set me wondering. Three days before I did it, and this is the second time of asking, I was diving into a swimming-bath. Suppose it had gone then instead of when I stooped to tie up the errant bootlace. Remember I was locked, immobile, rigid, on the drawing-room carpet. Suppose it had been the bottom of a swimming-bath. . . .

So here's a hint for the next pathologist faced with an inexplicable swimming-bath death. Have a look at the fourth and fifth intervertebral discs.

* * *

"You know," I told the garage man. "I may not know much about cars, but I'm no fool." He was a burly, jocular sort of chap and he eyed me with relish. "You don't need to tell me, sir," he said appreciatively. "We get all sorts here. Now about your car, what you want is a new engine. After all, so long as the engine's good, what does it matter how it looks? You'll have twenty thousand miles of care-free motoring." So a new engine it was. When it had been fitted I did notice a strong burning smell, but I put this down to the fresh paint in the cylinders. Then I broke down again. This time the garage electrician greeted me when I was pulled in. He popped his head under the bonnet and emerged with a charred wire. "I remember this job," he said gloomily. "I told the guv'n'r it needed re-wiring, but he's gone on engines. What I say is, what good's an engine without the wires to make it go?" I think the governor must have overheard this, because after a cursory glance he said: "Ah now, what you need is to have this old car re-wired. After all, if the wiring's good, what is there to worry about? You'll be good for twenty thousand miles of care-free motoring." At the time the words seemed rather familiar, but the goal was so greatly to be desired that I acquiesced. A few days later, when we were out en famille, the dear old car began to make a clanking sound, which I traced in the end to a screw adrift from the off-side rear wheel. I put it on; but after a quarter of a mile it came off. I put it on again; but after ten yards it once more broke loose. With misgivings I privily pocketed the thing and was congratulated by my missus on my skill in stilling the noise. When I took the car into the garage (a different one this time) I got the man to see to this at the same time as he mended a hole in the roof, reunited the choke wire, and sealed up a door that wouldn't close. Every week there's a list of little things like this, but the man has been very patient—he always seems glad to see me. Well, when I went to pick up the car, he drew my attention to a slow flat. "What you need," he pronounced, "is five new tyres." I was just going to agree nation had worked with such industry and skill that they had more than made up for the consequences of the war. Under the guidance and leadership of a Socialist administration Great Britain had advanced further on the road to recovery than any other nation in Europe involved in the war. In the last two generations a new type had emerged in Britain; virile men who realised that they had more to lose by failure and more to gain by success than any other section of the British community. It was to those people that the Government appealed, and they were confident that their appeal would not be in vain.

Mr. **Oliver Lyttelton** declared that the Government policy was to decrease by indirect means real wages and incomes. It had been misrepresented to the people that the social services would be in jeopardy from the Conservatives. Actually the social services were in jeopardy from the decrease in the purchasing power of money.

Mr. **Attlee**, in ending the debate, once more affirmed that the Government did not believe in slashing the social services. Their appeal to the people of this country was this: we have the finest social services that any country has ever had; their maintenance and preservation is a great incentive to all our people.

The Opposition amendment was rejected by 350 votes to 212, and the Government motion was then carried by 342 to 5. The House adjourned until Oct. 18.

The report and third reading of the National Health Service (Amendment) Bill will be taken on Oct. 19 in the House of Commons.

Public Health

LOCAL HEALTH AUTHORITIES AND TUBERCULOSIS

A joint meeting of the Society of Medical Officers of Health and the National Association for the Prevention of Tuberculosis was held in London on Sept. 15 under the chairmanship of Prof. R. H. **Parry**, president of the society.

A BALANCED SERVICE

Sir **Allen Daley** observed that real prevention of tuberculosis was founded on conditions of life—housing, general nutrition, and hygiene. Some years ago he had set out to find whether there was an inverse relation between the decline in tuberculosis and the rate of expenditure on hospital and medical services. No such relation had been discovered. The public-health service should concentrate on the basic conditions affecting the disease, with an especially close watch on nutrition. The second aim of prevention was the isolation and removal of the patient. In cases of tuberculosis the legal power under the National Assistance Act for compulsory removal to an institution was not of much practical value. The chronic ambulant infectious patient who was homeless presented a problem; local health authorities should consider providing special hostels although these would be difficult to manage and control, or alternatively people in houses with surplus accommodation might be persuaded to give rooms to such people. Children in contact with open tuberculosis should be boarded out on the Grancher system; some six hundred London children were being cared for on this ground, mainly in residential nurseries and schools.

Mass radiography was best placed under the control of regional hospital boards, provided that the local health authority advised on its best use; and he advocated X-ray examination of all people in regular contact with groups of children.

Regarding B.C.G. vaccination, if it was necessary to segregate children from infection for six weeks before and after vaccination, were they to be kept in camp schools or special hostels? Education must continue; and perhaps open-air schools and holiday homes would be the answer.

Aftercare requirements he defined as: (*a*) continued supervision of, and finding jobs for, the recovered cases; (*b*) Remploy factories and night sanatoria for chronic ambulant cases; and (*c*) care of semi-bedfast and dying cases, which were the most infectious. The service must not be allowed to become purely curative Ev if the hospitals were centres of treatment, they m have chest clinics as their outposts.

RURAL PROBLEMS

Dr. G. W. H. **Townsend** (Buckinghamshire) that in his experience district councils in rural a had made little use of the wide powers conferred them by the 1930 Tuberculosis Regulations. He thou that welfare work confined to tuberculosis was t consuming, and, it should be combined with that other conditions. At maternity-welfare centres mot waiting to see the doctor were learning all the f by lecture, film, or leaflet, whereas at the tubercu dispensary waiting was just waiting. Here was opportunity for health education on welfare-cen lines.

LOCAL HEALTH AUTHORITY'S POSITION

Dr. **Stuart Laidlaw** (Glasgow) said that evidence was wanted on the relation of overcrowding to tuberculosis. In Glasgow the contact-rate as bad in houses with 2–3 rooms as in those with rooms. The powers of removal under the National As tance Act had not been used because the psycholog effect would be bad.

He disagreed with the attachment of the ch physician to the regional hospital board. The eff had been concentration on the curative and clini aspects, and the domiciliary interest had waned. Glasg had a waiting-list for sanatorium beds of 1660, b there was no chance of admission unless the case w of special clinical interest. The medical officer of hea had no power to enforce admission, so a day-to-d battle was in progress to get cases away from danger home conditions.

He thought that the local health authority sho use B.C.G. through its own staff and regain direct cont of mass radiography. Segregation of children for B.C vaccination was being arranged, and home hel for tuberculosis cases were volunteering from among the relatives if they could be paid at the usual rates.

With regard to Sir Allen Daley's reference to hos accommodation, Dr. Laidlaw described how an em ward in a tuberculosis hospital had been reopened a hostel for 60 discharged patients who shared catering and domestic work.

HOUSES FOR THE TUBERCULOUS

Dr. W. **Alcock** (Burton-on-Trent) said, with rec to housing priority for the tuberculous, that 20 poi were essential to get a house and his department co give no more than 5 on medical grounds. Tubercul families should have a priority claim for rehou outside the "points" scheme. The best hope of co trolling the spread of the disease lay in raising the res tance of (*a*) contacts with active cases, (*b*) all you persons up to 25 years, (*c*) expectant and nursing moth and (*d*) other special categories liable to contra tuberculosis. For earlier detection, he urged repeat X-ray examination of all entrants to industry and t the Services.

B.C.G. VACCINATION

Dr. K. **Neville Irvine** (Henley-on-Thames) spoke o the need to segregate people for six weeks before an after B.C.G. vaccination. If the Mantoux test six wee after vaccination was not positive, there should be anoth test at ten weeks; some people were slower than oth in conversion. If, after ten weeks, revaccination wa decided on, a double dose should be used. Failure t segregate after the first vaccination did no harm; b some might contract the disease before immunity w established, thus damaging the reputation of this for of protection. Vaccinees should be warned about th papule which might appear after 2–3 weeks, and whi sometimes broke down to an oozing ulcer. Ultraviol light cleared up such persistent ulcers with dramatic speed. B.C.G. vaccination was never dangerous.

SOCIAL SERVICES

Miss **Anne Topley** (care almoner, Surrey) insisted that the social worker must be one of the chest-clinic team.

Dr. J. C. **Sleigh** (St. Albans) reported that his council had agreed to give absolute housing priority to the tuberculous where he so advised.

ntroduction of mobile chest clinics together with le motor transport for the patients to and from the . Such a mobile chest clinic, containing an X-ray ing set in a dark room, a dressing-room, and a small ting-theatre for collapse treatment, aspirations, ould easily be run in connexion with the existing, ly conveniently placed, "visiting station" and l provide all the diagnostic and therapeutic facilities t of radiography) of an up-to-date chest clinic. As I ed out, early cases could be admitted early for a stay at the sanatorium—or the hospital—and ment could be continued in these clinics, not too far the patients' homes. The quick turnover in the orium would soon cause waiting-lists to shrink to geable proportions.

is by the adoption of some scheme of early ambula- collapse treatment, after induction of collapse in torium or hospital, that the magic circle which ates most of our patients from timely treatment will roken. If such a new approach to treatment is ined with a more efficient use of mass radiography with large-scale immunisation, then—but only then can hope to control in our time "the last of the zymotic diseases of man in Great Britain."

ywood Hall Sanatorium,
olsingham, co. Durham.
E. G. W. HOFFSTAEDT.

VITAMIN E

R,—Opinion upon the efficacy of α-tocopherol min E) in the treatment of cardiovascular disease been, I am afraid, distorted by two factors.

he first of these is the attitude of some practitioners , not bothering to find out the proper method of inistration or type of product, yield to pressure the patient and simply prescribe any one of the y products in whatever dosage may come to the d of either doctor or patient and for any type of diovascular disturbance. Often the attitude is that en if doesn't do you any good, it won't do you any m." In this regard it should be pointed out that ients with heart-disease due to hyperthyroidism uld not be given vitamin E, since it aggravates this dition. Or if the patient happens to be a diabetic eiving insulin, his insulin dosage will be upset sooner later by hypoglycæmic symptoms. It should also be ed that the threshold dose of α-tocopherol usually between 200 and 300 international units daily, and t smaller doses will have absolutely no effect. No preparations may be given, because these inactivate tocopherol. I use a preparation which is a natural tillate and contains 100 international units of α-tocoerol per capsule. This product is enclosed in a hard psule which is timed to dissolve in about four hours in intestinal tract (rather than in the stomach) for more mplete utilisation and for elimination of gastric mptoms.

The second factor is concerned with aberrations of my iginal method which have appeared lately. Since my iginal observations on heart-disease, arterial obliterae vascular disease, and diabetes mellitus, certain rkers who began using vitamin E in the treatment of ese conditions have proposed "modifications" which metimes greatly hamper the success of this treatment. ne group in particular states that chronic rheumatic d hypertensive heart-disease should first be treated ith small doses and the dose gradually increased. In pport of this contention they say that if the initial sage is 300–400 mg. in a patient with rheumatic heart-isease, right ventricular failure will be aggravated or recipitated. They suggest that the left ventricle becomes ompensated before the right, and that this produces elative right-sided failure or aggravates pre-existing ight-sided failure. I have been treating these hearts with itamin E longer than anyone else and have not seen such esults clinically; and indeed it would require peculiar notions of the ætiology of right-sided failure to entertain this line of reasoning.

It has also been suggested that large doses administered to a patient with hypertensive heart-disease may raise the blood-pressure. Such an increase can be observed initially, but to anyone familiar with hypertension this need cause no alarm. Many hypertensive hearts in failure are associated with a blood-pressure lower than was present when they were compensated. On the administration of *any* compensating therapy, the blood-pressure will naturally rise, but it will not exceed the level before the onset of failure.

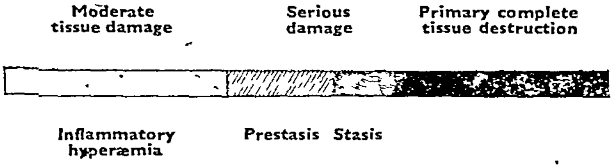
Another misconception is that digitalis must be discontinued if vitamin E is given. It is true that a patient cannot be digitalised by the "massive-dose" technique if he is already receiving vitamin E. The patient can, however, be digitalised in two days by simply giving small daily doses of gr. $1^1/_2$ digitalis folia or 0·1 mg. digitoxin. In general, the heart that needs digitalis also needs vitamin E.

It is to be hoped that this information will help physicians to use α-tocopherol properly, thus enabling them to arrive at a true evaluation of its usefulness.

London, Ontario. ARTHUR VOGELSANG.

VASCULAR STASIS

SIR,—Heat, cold, light, mustard oil, war gases, toxins, and many other agents may damage living tissue to various degrees, according to the dose applied. If the dose is large, or above a certain limit, the tissue may be completely and directly killed—primary necrosis. If the dose is small, the tissue damage is moderate, and the response may vary from a transient physiological reaction to a more severe complex pathological process. Between the two extremes is a state characterised by severe tissue damage with severe vascular reactions (see figure).



The vascular reactions may lead to the development of true stasis—a complete stoppage of the blood-flow in the smaller vessels—in the area involved. If stasis occurs, the tissue will suffer from ischæmia and secondary necrosis will result. As a response to doses below those which lead to stasis, a lesser, but still severe, vascular reaction is found—prestasis—which may lead to complete stasis if the tissue suffers further injury. The condition of prestasis is labile.

Usually the injuries are of moderate severity. In such cases intervention may shorten the process and aid recovery and repair. Where primary necrosis has ensued no therapy is of any use. If the minute vessels are in the state of prestasis, the tissue must be shielded against any further injury which may increase the vascular reaction. For example, a frost-bitten area must be protected against rough handling, protracted cooling, strong radiant heat, and ultraviolet light.

The condition of stasis is still more critical. In man stasis is in most cases irreversible; in lower animals—e.g., the frog—it may be reversible. Stasis is present in many important pathological conditions, but hitherto no intervention for the prevention or reversal of stasis has proved of value. The words of Lister,[1] some 90 years ago, still hold true:

> "But the number and discordance of the views entertained by different authorities regarding the cause of the 'stasis' of the blood in inflammation are sufficient evidence either that the subject demands further investigations or

---

[1] Lister, J. *Philos. Trans.* 1858, 2, 645.

when he added: "After all, they'd see you through for twenty thousand miles." That settled it; I got away as soon as I could find the starting handle. This was a fortnight ago; and I must own that I've had two flats since. Was he right, I wonder? I've asked the family, but, in the shiftless way of families, they seem to have lost interest.

* * *

It is many years since the *Victory* was towed away from its moorings in Portsmouth harbour and placed permanently in dry dock; but once again one of the old wooden walls is anchored there—the *Foudroyant*—and conjures up the days of Nelson and his famous signal. These inspiriting thoughts were shattered by a voice booming over her loud-hailer: "All those who want ice-cream come and get it."

* * *

Even if we do feel rather proud of the result of our operation for vaginal stenosis, it comes as rather a shock on holiday to see the front page of the *Sunday Mirror* featuring a photograph of the resulting triplets, and a laudatory caption (fortunately anonymous) about our skill in arranging the advent of not only one but three at a time.

The worst was to come, for our hospital's anonymity had not been preserved and the fan-mail had been collected for reply when we reluctantly returned home to work. Could we, asked one, provide similar service for herself, married 20 years and given up by all other doctors, for were we not the cleverest doctor in the world? "My tubes were removed 10 years ago," wrote another from even further afield, "could some artificial tubes be made?"

* * *

My grandmother once took on a young kitchen-maid at £8 a year; but the girl succeeded in Improving her Position by promotion to cook at £20 a year. Nowadays the labour exchange will have no hand in settling any girl in a resident post which offers a smaller reward than £100 a year. Partly, of course, the difference is due to the altered value of the pound, and partly—I hope—to an awaking conscience among employers. The most important cause, however—and it is not confined to Britain—is the opening now afforded by commerce and industry. Greater freedom is not the only reason for preferring office or shop or factory. In the days of our Victorian grandparents, when labour was cheap and plentiful, a draughty garret or a damp cellar was good enough for the servants to sleep in; and potato pie was often their provender, whatever the family might be eating. From this neglect has sprung the idea—still current, though no longer warranted—that domestic work is debasing. Indeed in one or two countries where these conditions have never prevailed, the housemaid's or cook's is still an esteemed occupation.

The only people who seem to be uninfluenced by the afterglow of the bad old tradition are those whose families helped to form it. Take our household, for instance. Our mother's help is a girl with a château in the west of France which has been in her family's keeping for many generations; and our daily comes of a local Titled Family. *My missus, being of a sociable turn of mind, has always* called a halt for tea and talk in the middle of the morning; and our present daily desists from peeling the veg. to prattle of cavorting with the Highest in the Land. It looks as if, thanks to our mother's help and our daily, our family can look forward to Improving its Position.

* * *

The man behind the counter grumbled when I asked for twenty penny stamps. "This continental method of buying stamps is getting very popular," he said. "A few years ago only foreigners bought stamps in tens, Britishers always asked for them in dozens. We have to alter all our mental arithmetic." I'm sure this proves something. Perhaps American economics have influenced us more personally than we realise.

The Piddingtons have been on at the Palladium. I hope that their act did not interfere with the Delta Rhythm Boys, who appeared in the same programme.

Letters to the Editor

CONTROL OF TUBERCULOSIS

SIR,—The admirable article of Sept. 24 by Mr .. who advocates B.C.G. vaccination in the most persua manner, will be welcomed by all who have the con of tuberculosis at heart. However, the risk of vaccinat to anybody still exposed to infection has to be Taking life as it is, this risk will "materially reduce field in which B.C.G. can operate, since it necessit pre-detection of the tuberculous household and remo of the infant at birth for some months."[1] No doubt t ultimate aim of control is the devaluation of the My *bacterium tuberculosis* from a potential killer to a harm saprophyte by rendering the host immune to it. M Francis is realistic enough "not to expect B.C.G. t produce such striking results," and to "recognise th there are many difficulties to overcome before this ai is achieved." Together with the long-range weapon *immunisation, we have to use the recognised* stratage of early diagnosis and early treatment.

It is untrue however, that "mass radiography languishing for want of an idea as to how it should used." During the past seven or eight years quite a fe authors have put forward constructive criticisms of t [illegible] scheme; and the council of t [illegible] for the Prevention of Tubercul has suggested a more enlightened policy for the futu What is required now, as Mr. Francis rightly observ is "the imaginative leadership of a campaign in which t weapons . . . will be used." But, alas, this leadership h so far not been provided, and any "change for t better has sprung from the ranks."[3] After many hig level discussions, working parties' reports, and p analyses, not a single nurse has come forward to sta any of the 5670 empty sanatorium beds in this countr *Waiting-lists are as long as ever,* and those patients wh have been diagnosed in time are missing their gold opportunity. Nor is there an efficient case-finding pr gramme; mass radiography is still *squandered* o picking up the random harvest from not very fruitf routine surveys on volunteers.

The alarming bed situation has led a few thoughtf and courageous chest physicians to consider "the ques tion of an alternative to sanatorium treatment." Various schemes of combined domiciliary and clin treatment have been devised in order to circumven the bottleneck of sanatorium accommodation. Th London scheme,[4] [5] where inductions are carried out i the patient's home, will not appeal to all chest physicians and it could not succeed in the hands of less experienced doctors. *The excellent* Glasgow scheme[6] depends o some hospital beds being at the chest physician's dispo for the induction of collapse, and on properly equipp clinics with at least screening facilities. These essentia prerequisites are often lacking in our provincial di pensaries, which, more often than not are mere "visiti stations."[7] On the other hand, the intended transfer o these clinics to outpatient departments of adequatel equipped local hospitals—with beds and X-ray faciliti at the chest physician's disposal—looks under presen circumstances like a dream belonging to the "Never never Land of long-term planning."

I have, therefore, recently suggested[8] that the most practical remedy for semirural and also for certain industrial areas where things are really bad, would be

TORSION OF APPENDICES EPIPLOICÆ

r.—I read with great interest the article by Sir Cecil eley and Mr. Childs in your issue of Oct. 1. In view e comparatively few recorded cases they were able d. may I report the brief case-history of a patient rated on three years ago ?

married woman, aged 26. with three children. was tted to St. Charles' Hospital in August, 1946. as a case of plete abortion. Her last menstrual period had ended 7 weeks previously. A dilatation and curettage was med and the following pathological report was received e material removed at operation : "Fragments of blood-hæmorrhagico-necrotico-purulent decidua and inflamed metrium." The first 4 postoperative days were uneventful. arly on the fifth day the patient complained of nausea pain in the lower abdomen and back. Her temperature, , and respirations were normal and her tongue moist coated. The lower quadrants of her abdomen were r on palpation. Findings at vaginal examination were stent with her gynæcological condition. At laparotomy urs later a twisted and gangrenous appendix epiploica e transverse colon was found and excised. The abdominal d healed by first intention.

EXCISION-SUTURE TECHNIQUE IN INFECTIONS OF THE HAND

R.—In answer to Mr. Ross's letter of Sept. 3, we ld emphasise the following points :

We have at all times made a careful search for gns ; in our experience they are often present early, icularly in pulp infections.

. The risks of lymphangitis or septicæmia following method are small even without chemotherapy. h chemotherapy these complications are completely vented.

. In none of these cases did we incise a cellulitis : ll 99 cases open pus was obtained.

Unless we felt certain that pus was present, the was treated conservatively by immobilisation and motherapy.

. The main advantage claimed for this method is y healing, comfort to the patient, and early recovery unction.

CHLOROMYCETIN IN ENTERIC FEVER

IR,—I read with great interest the letters last week Dr. Kiledjian and General Tutunji. I was specially erested in case 1 reported by Dr. Kiledjian because le is known as yet about the action of chloromycetin paratypoid-B fever.

The only other report I know of is on a series of ases briefly described by Christie.[1] I should therefore e to report the following case.

A single woman, aged 46 years, was admitted on Aug. 20 s year. She had been taken ill with general malaise, severe adache, and fever on Aug. 14, the day after her return m a holiday in Majorca.

On admission her temperature was 100·1°F, and pulse-rate per min. The tongue was coated, and she looked dis-ctly toxic. There was no bronchitis. The abdomen was a tle distended, with tenderness and gurgling over the cæcum ; e bowels were costive. The white-cell count was 6700 per mm., with 81% polymorphs.

She ran a continuous fever around 102°F. and on Aug. 23 o rose spots appeared on the abdomen. Blood-culture on at day gave a growth of *Salmonella paratyphi-B*. Agglutina-ons were positive for that organism in dilutions of 1/640 "H" d 1/20 "O." Stool and urine cultures have been negative roughout.

Treatment with chloromycetin was started on the evening of the 27th (13th day of the disease), with an initial loading dose of 4 g., followed by 0·25 g. 3-hourly. There were no untoward effects, but the fever continued. On Aug. 30 the dose of chloromycetin was stepped up to 0·5 g. 3-hourly. The next day the temperature fell by crisis and has remained normal since. On Sept. 3 the dose of chloromycetin was reduced to 0·25 g. 3-hourly, and treatment was discontinued on the 7th. A total of 34 g. was given.

All blood-cultures subsequent to chloromycetin treatment have been negative. The organism recovered from the culture of Aug. 23 proved to be twice less sensitive to chloromycetin than a strain of *S. typhi* held in the laboratory.

This case shows that chloromycetin has definite therapeutic action in paratyphoid-B fever, but that the dosage required may be greater than that for treatment of typhoid fever.

I wish to thank Dr. J. Alston, of the Archway Group Laboratory, for the pathological investigations.

Highlands Hospital, London, N.21.　E. MONTUSCHI.

THE REGISTRAR'S SALARY

SIR,—Your correspondent, Dr. Gee (Sept. 24, p. 580), invites several comments. From his own account he appears repeatedly to have fallen on his feet. He qualified after the war was over and gained the M.R.C.P. diploma at an unusually early stage of his career. He has been in the Services, presumably as a specialist, for two years only. Since demobilisation he has been allowed to work hard (which is what I take it he means by "ruining my health"). He complains that of his salary (£7 16*s*. 2*d*. a week) 9% must be spent on books and subscriptions necessary to the maintenance of his standards. Why the "must"? He should do pretty well in this line for £36 a year. Subscription to the B.M.A., THE LANCET, the Royal Society of Medicine, and a couple of the specialist publications should not set him back more than £12.

He is set with his foot on the second or third rung of the ladder and he jumps off because he cannot manage to live on £600 a year *net*. Passing over the problems of clergymen and schoolmasters, who seem to manage somehow on far less, may I remind him that there are many others in the queue hoping one day to fill the mythical "shortage of specialists?" These people qualified even before the war, spent five years or more uncomplainingly as R.M.O.s or squadron medical officers, acquired two or three children and a car also, and have lived on "subsidised cups of tea" for two or three years at a salary of £450 rising to £650 *gross*. Under these conditions they have gained higher degrees and diplomas, and engaged in original work. However desperate their case has seemed, their sense of vocation has kept them hoping. Surely money is not everything in medicine. A congenial job is at least as important.

As I am still breathing, may I sign myself

DUM SPIRO SPERO.

SIR,—It is to be hoped that your correspondent of Sept. 24 will not remain embittered for life at a "system" which has deprived him of the glittering prizes of a specialist career. I venture to suggest that in six months' time the gilded vision of such a life as he has no doubt conjured up will have faded considerably, and that general practice will appear to him not such a bad way of doing medicine.

However, a word of warning. The "comparative opulence of general practice" of which he speaks is a myth, at any rate under the National Health Service. He will find that exchanging even a small town flat for a house from which to practise carries with it increased financial commitments which rapidly swallow up any increase of income. And if he found work as a junior registrar in hospital ruinous to his health, then a winter in general practice will surely drive him to his grave !

else that it lies beyond the reach of human means of research."

To improve the treatment of damage due to cold, heat, actinic insults, toxins, and many other agents, a systematic study of the prevention or reversal of stasis is of fundamental importance to clinical medicine.

Institute of Pathology, University of Oslo. LEIV KREYBERG Director.

CONCENTRATION OF DIPHTHERIA ANTITOXIN IN CORD BLOOD

SIR,—It is regrettable that Miss Barr (Sept. 24, p. 578) missed the main point of my letter of Sept. 17. My intention was not to criticise these workers' technique but to call attention to a universal biological phenomenon of which their material provided a special example.

Whatever antibodies are present in the cord blood have not been formed by the fœtus in utero, but were derived from the mother by placental filtration; in addition, only univalent antibodies can traverse the placental barrier, whereas bivalent antibodies cannot. Filtration of antibodies continues until an equilibrium is set up—namely, when the titres in maternal and cord sera are equal. It is manifestly impossible, therefore, for the cord sera titres to exceed the maternal sera titres, unless one makes the unlikely assumption that after equilibrium had been reached antenatally, the maternal antibody titre began to fall and that the reverse process of filtration of antibody from the baby to the mother lagged behind.

Whenever findings seem to conflict with an excellent theory it is a good idea to re-examine the data. Even conceding that the laboratory error does not exceed 10%, it is easy to see how a bias of considerably greater magnitude could arise. For example, if all the maternal sera are examined on one day using one animal, while all the cord sera are examined on another day and using another animal, the results would not be strictly comparable. Since the protocols are not available to me, it is of course not possible for me to state what bias if any existed in the present study.

New York. A. S. WIENER.

DANGERS OF LEAD NIPPLE-SHIELDS

SIR,—Lead nipple-shields, unfortunately, are comfortable to the nursing mother. They are pliable and fit like a cap on the nipple. Their danger is set forth in the article by Dr. Gordon and Mr. Whitehead in this issue. They are widely used and readily obtainable in chemist's shops. In London they are advocated in large maternity units, including at least one important maternity hospital. In the North of England, we are informed, sales are even larger, and in the Midlands they are recommended in a neonatal unit famous throughout the country.

The reason given for their use is that the lead assists the healing of cracked nipples; and so it does, but unfortunately this process occurs at the expense of administering lead compounds to the suckling infant at every meal. We have been told that the use of the shields is recommended only for a week or two, but even so the danger remains. On inquiry we found that mothers who like the shields do in fact take them home on discharge from hospital, and that they are able to obtain them free under the provisions of the N.H.S. Act.

The usual form of chronic lead poisoning in the infant is lead encephalopathy, and Dr. Gordon's article indicates that complete recovery of an infant from this disease is unusual. Generally the infant dies or is rendered mentally defective. It is a disturbing thought that, among the many infants one sees with fits and mental defect, one may easily have missed cases of lead encephalopathy through failure to bear in mind the possibility of lead poisoning. The use of lead compounds in industrial processes is hedged about by strict legal in order to prevent poisoning. There is, we suggest, room for doubt that the sale of lead nipple-shields be made illegal.

The Ministry of Health has issued an urgent against using these shields; and we acknowledge generous help received from two large firms stopping their sale. Plastic nipple-shields, which now on sale, might well be given a trial by th recommending the use of a shield. We appeal to doc and midwives to do all they can to abolish the us this dangerous metal in nipple-shields for nursing moth No mother would risk using them if she knew the

London, E.2. DONALD HUNTER.

MIDWIFE AND/OR DOCTOR

SIR,—In your leading article last week you have succeeded in being entirely objective.

With regard to your comments on the moth supposedly mistaken preference for a doctor as analge surely the present-day general practitioner is chang over very rapidly to the use of the Minnitt "spec attachment" and even more rapidly to tric frequently combined with pethidine. Even, ho if he still uses chloroform there is no evidence that i practice this delays delivery as you suggest. Bourne Williams[1] state: "When chloroform was used as a rout for every delivery at Queen Charlotte's Hospital th was found to be no increase in the time of labour, unchanged forceps-rate, no greater incidence of p partum hæmorrhage, and no greater stillbirth rate."

Rightly or wrongly the midwife is not allowed to any of these aids and she realises that her own Min apparatus without attachment is already out of d and out of favour with patients who have experience other methods. What woman doctor or doctor's would deny herself one or the other? Dr. Grantly Di Read does not deny them if requested and incidenta is himself present at the confinement. How else co he have made his observations and added to the s of our knowledge?

Surely if the maternal-mortality rate for cases supe tended by the Queen's Institute of District Nursing 0·74 per 1000 births—includes those transferred general practitioners as "aid cases," the latter can have dealt with them so incompetently; yet in the nex paragraph dealing with the admitted deficiencies in th general practitioner's training you imply that Sir Eard Holland's investigation applied only to booked doctor cases. I have not the report by me, but was this so?

Surely, Sir, the answer lies in the will to cooper between midwife and doctor, the latter's part in a norm case being mainly with analgesia. But how can a doct be "available in an emergency" such as a catastroph postpartum hæmorrhage unless he is in the hou We cannot do without each other. In this area the la Dr. R. E. Moyes and his colleagues themselves estab lished the professional position of the midwives by refusing to attend a case at which a trained midw was not in attendance, and so put an end to the era the handywoman; but he did not forget the importance of the presence of the practitioner during labour; and you would do well to re-read his paper[2] to apprecia the part played by the general practitioner in improving domiciliary midwifery.

Amble, by Morpeth, Northumberland. R. P. ROBERTSON.

*** We should have made it clear that Sir Eardley Holland's investigation covered all the maternal death (100) notified in a county during three years.—ED. L.

y doctor with his fuller background knowledge. the patient is unable to judge between conflicting ons. It is well that the patient should have access her sources of medical opinion, but danger lies in absence of direct contact between the sources of e.

the health centre of the future it may be possible corporate the welfare and school medical services e general-practitioner organisation. and to arrange liaison between the industrial medical officer and health-centre team. Meanwhile the gaps between bricks of a good medical service must be filled in he mortar of determination to keep the other fellow the picture," and extended facilities for verbal and en contact are needed. While no mechanical means tercommunication can replace direct personal contact een the general practitioner and his colleagues. eve that an improvement in written contact might fected on the following lines.

e 7 in. by 5 in. National Health Service record lope is now practically universal. I suggest that medical units—specialist. practitioner. and local th authority—adopt a standard size of headed e-paper designed to fit unfolded into the record lope. The top edge of the sheet should be gummed the sheets made up into block pads. Such pads ld make duplicating of notes with carbon paper less: the duplicate would be posted "for information to the general practitioner, who would affix the s or reports in date order to the back of a continuation t. They would remain a permanent and useful rd, and the envelope would no longer be a swollen ainer for a jumble of reports of different size and shape. ith some such simplification of recording outside the pital as well as within, Mrs. A on her next attendance surgery might receive from her own doctor the added efit of a colleague's advice interpreted in a way she understand.

[illegible] R. J. F. H. PINSENT.

LOWANCES FOR PROFESSIONAL WITNESSES' FEES

R.—In your issue of June 4 I drew attention to iculties in connexion with the payment of fees to ried medical and dental officers for attending the minal Courts to give professional evidence.

n the final paragraph of that letter the hope was ressed that the offending paragraph of the Home ce circular (no. 189/48, dated Aug. 28, 1948). addressed clerks of assize. clerks of the peace, and clerks to the tices. would be revised. This hope has now been filled by the issue of Home Office circular no. 190/49, ted Sept. 8, 1949, which reads as follows:

"I am directed by the Secretary of State to refer to the cluding sentence of paragraph 5 of the Home Office ular of 28th August. 1948 $\frac{\text{(H.O. 189/48).}}{\text{C}}$ and to say that has been in consultation with the Minister of Health ut the payment of professional witness allowances to aried officers in the National Health Service, such as cialists and hospital doctors. who do not lose any income attendance in court. He understands that the Minister now prepared to allow salaried hospital medical and dental ff in the National Health Service to retain any fees which ay be paid to them for professional services not within e scope of the hospital and specialist services and that tendance at court as medical witnesses is regarded as professional services which are not included within the scope of e hospital and specialist services. In the circumstances e Secretary of State considers it reasonable that professional tness allowances should in future be payable to all salaried spital doctors and dentists in the National Health Service: at paragraph 5 of the Home Office circular should be ended accordingly."

Obituary

ROBERT MILNE

M.D., M.S. LOND., F.R.C.S.

Mr. Milne. consulting surgeon to the London Hospital, will long be remembered with respect and liking. His surgical opinion was sound: his technique was good; and he succeeded in mastering a specialty while remaining a general surgeon. Moreover, he taught ably both by precept and example. embodying for his students much that was most valuable in their hospital's tradition.

Born in London in 1881. he was named after his father. Robert Milne. M.D.. medical director of Dr. Barnardo's Homes for some forty years. He entered the London Hospital in 1899 with a Price scholarship. and qualified in 1904. taking the London M.B.. with honours in medicine. in 1905 and the F.R.C.S. in 1906. From 1905 onwards he worked with T. H. Openshaw in the orthopædic department. and after joining the honorary staff in 1910 he spent some time in the United States. largely in Albee's clinic. On his return he was one of the first in this country to use Albee's method of spinal fixation.

Having served in the R.A.M.C. during the first world war. with the rank of major. Milne returned to the London Hospital and in 1922 succeeded Openshaw in charge of the orthopædic department. As a general surgeon. he did not follow the general trend towards separating his specialty from the rest of the hospital's surgical practice. but he was always willing to give his colleagues the benefit of his immense experience. which extended to radiological and electrical techniques. His knowledge of diseases of bone was exceptional and his opinion was in constant demand in the interpretation of difficult X-ray films. His work as surgeon to Dr. Barnardo's Homes gave him an insight into the rarer surgical diseases of childhood.

"Robert Milne." writes H. S. S.. "was essentially a London Hospital man, and only those who were his colleagues could appreciate all that he did for the hospital. for the students, and for the great branch of surgery which he made his own. He was I suppose one of the last general surgeons to make a mark in orthopædics. and although he refused to abandon the wider field it was in the surgery of bones and joints that his real metier lay. and for it he showed a rare and convincing aptitude. His plain common-sense outlook on its problems was appreciated equally by his patients and his students. many of whom look back upon his outpatient sessions as a revelation of what can be done by simple methods. His teaching was never over their heads but always went to the heart of the matter and won their confidence." "To the mere dresser." adds L. N. J.. "Bob Milne was the kindest and friendliest of chiefs. giving an impression of quiet and unassuming omniscience in his subject. One never saw him stumped. rattled. or ruffled. and his courteous and assured manner. especially with small patients and their anxious mothers, spread an air of justifiable confidence all round. Like so many Scotsmen he was full of quiet humour. And none had a sharper eye for orthopædic humbug—'operations which left the patient no better off except that he could perform some little parlour trick.' as he put it in a voice curiously and unexpectedly high-pitched for so sturdily built a man." As an examiner, he was kind. and always referred to the examinee as "Boy." His humour often lessened the tense atmosphere which surrounds the nervous candidate and helped to put him at his ease.

It is now six months since I left a registrar's post in a teaching hospital to enter general practice, and so far I have not regretted it. After qualifying in 1940, serving three years as a medical specialist in the Army at the latter end of the war, followed by two years as a registrar, and having obtained the requisite higher qualifications, one felt oneself to be in the running for specialist appointments. But advertisements for such posts have been almost non-existent over the past eighteen months, and for those vacancies which have occurred a field of fifty applicants has been by no means uncommon. The chances of obtaining the membership used to be considered small at 10 to 1 against, but what of a 50–1 chance against success! The alternative prospect of becoming a "stooge" under the grandiose title of senior hospital medical officer did not attract me, and so general practice seemed the obvious choice.

My experiences, small as they are, suggest to me that it is high time this mad rush for specialisation is checked before it ruins the profession. It is obvious that there are many more highly qualified young men holding registrar appointments than there can ever be specialist vacancies to fill, and many will have to take the plunge into general practice sooner or later.

There is still plenty of opportunity for good clinical work in general practice, despite the pessimists who maintain we spend our days filling up forms for milk, spectacles, and corsets. I find nine years of hospital practice astonishingly helpful in the treatment and nursing of pneumonias, cerebral thromboses, &c., in the home, and in the country most acute-medical conditions can be looked after at home. One finds ready coöperation with a first-class provincial hospital if the elementary courtesy of a sensible letter is observed in sending outpatients, or ringing up the appropriate department of the hospital for emergency admissions. Admittedly midwifery has been a little frightening after a lapse of nearly ten years, but excellent tuition is forthcoming from two indulgent partners. Interesting cases do not occur only in hospital but abound in general practice if one takes the trouble to look for them.

The success of a health service depends on a high standard of general practice. Of recent years there has been a tendency among the newly qualified to regard general practice as the last refuge of the destitute unable to find a niche in hospital. For this the teaching hospitals are largely to blame. Professorial chairs are all very well to encourage research and academic progress, but the presence of so many academically brilliant young men in the medical schools is a temptation to encourage the erudite and scorn the commonplace. It may be most stimulating to discuss the ætiology of pseudo-fibrillary twitchings of the pituitary but it is far more important for the student to learn how to diagnose and treat Mrs. Smith's belly-ache. I feel that if the needs of general practice were borne in mind more by those responsible for medical education—which implies that general practitioners should have a say in the syllabus—there would be far less reluctance on the part of newly qualified doctors to enter general practice, and far fewer disillusioned young men eking out a pauper's existence in a garret with starving wife and children while vainly searching the advertisement columns of THE LANCET by the light of a guttering candle for the most perfect but most elusive of all jobs, that of a hospital specialist.

Lest anyone should imagine that the life in general practice here advocated is without blemish, it would be wise to add that there are many frustrations; patients can be infuriating, and it is a dog's life for one's wife. But at least one can have the satisfaction of being a doctor in the fullest sense and not just a specialist in the function of one part of one organ.

A. S. WATTS.

Mortimer, Berks.

EXPERIMENTS ON ANIMALS

SIR,—I was much interested to read the comment Duncan Leys and D. R. Newth (Sept. 10) on the quest of experiments on children and feel that many b myself must share their ethical views. Boys of 1 cannot be regarded as of such an age as to give con or realise the full implications of an experiment. many instances in which children have been as experimental material have been recorded in medical journals. One cited in your issue of Sept. (p. 569) concerns the transmission of "rubella to by injecting subcutaneously the filtered throat from established cases; of 16 children presumed tible and injected in this way, 4 developed typical while 2 showed the characteristic leucopenia and lym adenopathy without rash."

It does not seem at all clear whether such experim involving a certain amount of risk to health in child are considered ethical by the General Medical Counci this country. In 1935 I wrote to the G.M.C. about so American experiments in the *transmission* of mumps, which "thirteen supposedly susceptible children 4 immunes had their mouths sprayed with an emul of an infected monkey parotid gland" (*Lancet*, 19 i, 504). Of these susceptibles 6 developed mild but unm takable mumps, 3 had doubtful symptoms, and remained well. I asked the G.M.C. (1) whether they wo consider these experiments justifiable, (2) whether th was any obstacle to their repetition in this country, (3) whether, in making such a test it would be consider ethically sufficient to obtain the consent of the par or guardian? The reply, dated March 8, 1935, was th the president of the council considered that "it does n fall within the province of the Council in the exercise their jurisdiction under the Medical Acts to advi registered medical practitioners on questions such those raised." So for the present the practitioner is in the dark as to whether experimentation on childr comes under the heading of "infamous conduct" not. On the other hand, we are all entitled to our o opinions on the matter.

M. BEDDOW BAYLY.

Camberley, Surrey.

SEEING THE PATIENT THROUGH

SIR,—In your issue of Sept. 17 Dr. Lipscomb h very ably drawn attention to the evils arising out lack of coördination between individuals and depa ments in hospital practice. The evils that he describ are, however, perhaps greater outside the hospital wa than they are within.

In the past the family doctor was regarded as the on source of medical advice directly available to the patie At present, besides the general practitioner, there three or more sources to which a patient may turn medical wisdom, and which may supply conflicting even contrary advice.

Mrs. A's pain starts at work, and she is referred by works' nurse to the industrial medical officer.

Mrs. A's symptoms accompany her first pregnancy, she lays them before the medical officer at the welfare cen which she attends for antenatal examination. Her pregna may go to term and an unexpected complication arise dur labour. As her own doctor is not on the obstetric list, second general practitioner, to whom she is a compl stranger, is called in by the midwife.

Mrs. A may experience her pain while shopping a remember that the hospital casualty department is just rou the corner. She can see the doctor there.

In addition Mrs. A's child may have frequent sore thro and enlarged tonsils. She has heard that the waiting-l for tonsillectomy is shorter at the school clinic than at hospital to which the child has been referred, and the ch is seen by the school medical officer.

The advice given by these different doctors, thou sincere and sound, may differ from that given by

Notes and News

CLOTHES AND PSYCHIC HEALTH

THES. said Mr. James Laver, at the opening of the session London School of Medicine for Women, on Sept. 30, never been designed for utility. Originally they were al—fertility symbols—and perhaps that was their last tion with anything even remotely connected with al health. Doctors have had as little effect on clothes alists on manners. When the S-shaped woman came in. time of the bustle, the health corset was launched; no time it had become tighter (and smarter) and less y. People, he finds, wear too many too tight clothes; ese are designed on one of three principles: the hier-al principle, emphasising class distinction, commonly in the clothes of men; the seduction principle, designed ter sexual attraction, commonly found in the clothes of n; and the utility principle, which has very little to the matter. It prevents women wearing crinolines of rds' circumference but not those of 6 yards' circumfer- it prevents men from wearing clothes which stop them ing entirely but not from wearing clothes which nearly them breathing.

men's clothes fluctuate so much that there is always a e that they will be sensible from time to time. There chance that men's clothes will ever be sensible. They ssilised. The buttons on the sleeves of his coat, he said, not been used since 1795. At the back of evening "tails" no more vestigial buttons, used in an age of horse-riding tton back the skirts of the coat; but the skirts themselves peared in 1780. The only way to change men's clothes is to bring in a new sports dress. This in time becomes ng dress, and then servants' dress, for servants wear the off dress of their masters in every sense. The 19th-ry footman wore 18th-century dress; and the evening of the 19th-century gentleman is worn by waiters in 0th. Young men now wear sports coats and grey flannel in twenty years, when this costume has got smarter—and fore tighter—it will be correct dress, and something like American lumber-jacket will be coming up on the left. en marry the men who look likeliest to support a family, correct men's dress today is designed to show that the er doesn't work with his hands. Men dress like bankers, h gives a great sense of security. Women's dress ranges gh a cycle in which modes are successively labelled tent, chic, usual, dowdy, quaint, romantic, beautiful. if the emancipation of woman has at last been achieved, permanently achieved, it may be that they will be able oose men as men, and not as symbols of security. In case all the women may wear dungarees, while the men dress as spivs.

at clothes can influence the mind as well as express it. on always put on a full court dress to write—as anyone tell, Mr. Laver said, by comparing his style with that of ac, who always wrote in a dressing-gown. There is ething to be said, he believes, for what the French call t. To treat the body alone is merely to treat symptoms: mind must be treated too. Gin may be bad for the body: if it changes a tired and disagreeable husband into a onable person it is not entirely harmful. A smart hat makes fference to a woman: and an ailing neurote has some-s been changed to a useful citizen by finding the right smaker. He urged his hearers to pay attention to this in professional lives; for if our age is to get greyer and er, then the future for women is a beige one. Most people, erneath, are desperately frightened; and he finds some-g gallant in the way the human spirit tries, with its ners and its funny little hats, to reinforce the love of life.

AN AMERICAN VIEW OF REABLEMENT

t the Royal Free Hospital, on Sept. 14, Dr. Howard Rusk. the Bellevue Hospital and the Institute of Rehabilitation. w York University, spoke of the enormous cost, in wealth and ppiness, incurred by failure to secure proper rehabilitation er industrial and other injuries and illnesses. He spoke chiefly cases of hemiplegia, spastic paraplegia, and quadriplegias, tailing the various tasks which make up the routine of patients' lives at his clinic. The tasks are set out on a m provided to each patient. As the patient finds himself le to carry out each fresh task, such as his toilet, and moving m a wheel-chair to bed and from bed to wheel-chair, the propriate blank on the form is filled in so that the patient may see his progress in pictorial form. This method has succeeded so well in promoting the competitive spirit that, with various mechanical aids, even quadriplegics have been able to return to some form of employment.

RHEUMATISM AND THE PUBLIC

THE British Rheumatic Association has lately held a two-day conference and exhibition. This association, consisting primarily of lay sufferers from rheumatic diseases, was formed two years ago to further the interests of all such sufferers in the political, social, and economic fields: its activities are correlated with the medical work of the Empire Rheumatism Council. The association's latest meeting, held in London on Sept. 27 and 28, covered a wide field. In the exhibition many bodies, such as the Chartered Society of Physiotherapy, the Association of Occupational Therapy, and the Central Council for the Care of Cripples, were represented at stalls in which the activities of these bodies in the care of the rheumatic patient were described. The spas too were represented and photographic exhibitions illustrated their work.

The conference met at two sessions. At the first Dr. W. S. C. Copeman lectured on recent advances in the treatment of rheumatoid arthritis, with particular reference to 'Cortisone.' In the subsequent discussion he had to contend with many questions from enthusiastic lay seekers after the truth. At the second session Dr. W. S. Tegner and Dr. A. B. Williamson, of Leeds, spoke on the Care of the Rural Patient. Dr. Tegner approached the topic mainly from the aspect of improvisations that can be made in the homes of rural patients who need physiotherapy, while Dr. Williamson reviewed the organisation of peripheral rural clinics. The discussion which followed revealed general agreement that the Government should be pressed to provide treatment facilities for rural patients.

The young association is finding its feet and enlarging its activities. It is bound to come more and more into touch with the medical profession; it will have to be guided wisely and carefully if it is not to fall a prey to the enthusiasm of unorthodox concepts of ætiology, pathology, and treatment. Rheumatism remains an all-embracing term, and it would be of interest to ascertain exactly what forms afflict the members of the association, who have banded themselves so hopefully together.

University of London

On Oct. 19, 20, and 21 at 5.30 P.M., at University College, Gower Street, W.C.1, Sir Paul Fildes, F.R.S., will lecture on Growth and Reproduction of Bacteria. On Tuesday, Oct. 25, at 5 P.M., at St. Mary's Hospital medical school, W.2, Prof. C. F. Schmidt (University of Pennsylvania) will speak on the Physiology and Pharmacology of the Cerebral Circulation. On Nov. 21, 22, 23, and 24 at 6 P.M., at the London School of Hygiene, Keppel Street, W.C.1, Sir James Learmonth will give four lectures on the Contribution of Surgery to Preventive Medicine.

University of Sheffield

At recent examinations the following were successful:

M.D.—Helen N. Mellanby, E. L. M. Millar.

Final Examination for M.B., Ch.B.—Daphne Burkinshaw, Nancy Cole, J. D. Crabtree, Peter Kelly, Barbara Kilpatrick, P. O. M. McGirr, Shamina Mohamedi, F. L. Myers, G. H. Pagdin, Kathleen Sampson.

University of Aberdeen

On Sept. 28 the following degrees were conferred:

M.D.—G. S. Riddell (with honours); W. F. Russell.

M.B., Ch.B.—W. I. Cranston (with honours); J. G. Henderson, G. G. Mathieson, W. W. Wilson (with commendation); B. C. Abernethy, Isobel B. Alexander, John Barron, A. A. W. Boyd, Katharine M. Brodie, Margaret M. Chrystall, Francis Clark, I. M. Cochran, William Cochran, I. A. Cook, F. T. Crossling, H. J. Crow, G. M. Davidson, Jean L. Davidson, Kathleen M. Dawson, B. W. Duthie, E. A. Fox, A. B. Fraser, D. E. Fraser, D. M. Fraser, Doreen M. M. Gove, R. B. Gove, Alexander Hird, J. D. Hunter, J. C. S. Jeffrey, Jean D. Jockel, F. F. Kinnaird, James Knowles, I. H. Lewis, Alan Lorimer, A. M. McGregor, J. A. McGregor, Yvonne M. H. McGregor, Mairi E. Macleod, D. K. McTaggart, W. G. C. Manson, A. T. Mennie, R. S. W. Middleton, Charles Miller, Frances F. Milne, G. A. W. Milner, R. W. Milner, Norman Murray, W. D. Nicholson, Helen R. Phemister, J. W. Price, P. E. Rixon, James Rose, Catherine I. M. Ross, R. G. Ross, W. A. Ross, G. S. Selbie, R. M. Sinclair, R. A. Smith, Eileen M. Spence, Doris L. Stephen, G. S. Stirling, Isobel R. S. Troup, R. G. Troup, Margaret F. Tweddle, D. C. Watler, G. L. Watt, Kathleen M. Watt, A. A. Will, G. A. Wood, Constance M. Yule, R. M. Yule.

University of Birmingham

Dr. Francis Braid has been appointed Ingleby lecturer for 1950.

Milne remained on the active staff of the London Hospital till 1943. Writing of his war service, C. P. G. W. says: "While the blitz of London was at its height he carried on his work in a fearless and unruffled manner which was a joy to behold. Though he had served in the Royal Army Medical Corps, he always had a soft spot for the Navy. He became consulting orthopædic surgeon to the Navy shortly after the commencement of the second world war and in 1942 was appointed a temporary surgeon rear-admiral, a post he filled with dignity and honour. He was always ready at a moment's notice to fly anywhere to see any urgent cases. He never spared himself. The medical branch of the Navy loved him because of his willingness to give advice and to give it in a most friendly manner. He would operate on the difficult case or help the younger man, acting invariably as the assistant. This attitude was appreciated immensely by all who sought his advice.

"Milne was a family man who loved his home and always gave a ready welcome to anyone who would drop in for a talk or a meal. It was a joy to see the family circle with Robert chipping the entire company. At the London Hospital dinner last year he was in the chair, and all those present will remember his able and stimulating speech enlivened with whimsical humour."

Our brief report of that speech deserves quotation because it reveals so much about the speaker:

> "People had the idea," he said, "that hospitals are places to which patients go for perhaps four weeks, and then pass on; to which students go for perhaps four years, and then leave forever; a place where ships pass in the night. But this was not true; a hospital was a place of continuing friendships and lasting memories—memories of chiefs who bullied you when you were a houseman and of housemen who bullied you when you were a chief. The London Hospital, for all its internal changes, still stood exactly where it did; and on emerging from Whitechapel station one could still detect the faint smell of coffee and human unwashedness described by Henry Bashford 38 years ago. The hospital's ambition was to produce a thoroughly sound doctor, to be depended on in emergency, who would do the right thing even if he didn't quite know why. It had produced great men of science, like Henry Head and Hughlings Jackson, but also men of great service like Barnardo and Grenfell. He had a faint fear that in the new system unselfishness and the spirit of service might be snowed under, but he asked his hearers to drink the hospital's health in the hope that they would continue."

Mr. Milne died at Aldeburgh on Sept. 29. Of his family of three, the elder son has qualified and the younger is a medical student. Miss M. G. Milne, the matron of St. Mary's Hospital, is his sister.

NICHOLAS KEATING

O.B.E., L.R.C.P.I.

Dr. Keating, who died at his home in Dublin on Sept. 23 was, till last year, senior member of the Silicosis Medical Board at Cardiff. After qualifying from University College, Dublin, in 1912, he held house-appointments at Chesterfield and North Derbyshire Hospital. Later he became assistant tuberculosis officer and assistant school medical officer for Sheffield till in 1930 he joined the silicosis board. He took part in two special investigations—one on the incidence of silicosis in granite-workers and the other on the incidence of pneumoconiosis in coal-trimmers in ships—and he was also a member of the advisory committee on the treatment and rehabilitation of coalminers which sat in 1943. Last year he was appointed O.B.E. for his services. He retired a year ago because he felt he was blocking the way for promotion of younger men.

A colleague adds: "Keating was well known to doctors in South Wales, whose patients applied to the board for compensation for pneumoconiosis. Although somewhat diffident in advertising his ability he had a reputation as a sound diagnostician. An easy and pleasant colleague to work with, he was as interested in the pneumoconiotic as in pneumoconiosis, and Welsh miners everywhere testify to his humanity."

Diary of the Week

OCT. 9 TO 15

Monday, 10th

UNIVERSITY OF LONDON
5.15 P.M. (University College, Gower Street, W.C.1) J. Z. Young, F.R.S.: Structure of Peripheral Nerve. of two lectures.)

Births, Marriages, and Deaths

BIRTHS

CRITCHLEY.—On Sept. 30, in London, the wife of Dr. J. Critchley—a son.

CRUICKSHANK.—On Sept. 25, the wife of Lieut.-Colonel J. [illegible] .C.—a daughter.

[illegible] the wife of Dr. I. H. Gosset—a son.

[illegible] 23, at Reading, the wife of Dr. R [illegible] *Hargrove—a daughter.*

HAWKINS.—On Sept. 30, in Birmingham, the wife of Dr. Cli Hawkins—a daughter.

HOOD.—On Sept. 26, the wife of Dr. Ronald Hood—a son.

MACKENZIE.—On Sept. 24, the wife of Dr. E. H. MacKenzie—a s

MARSHALL.—On Sept. 28, at Wolverhampton, the wife of Dr. A Marshall—a son.

NASH.—At Ladysmith, Natal, the wife of Dr. R. W. Nash—a

NEAL.—On Sept. 26, in London, the wife of Major J. B. N R.A.M.C.—a son.

SALEH.—On Sept. 28, in Manchester, the wife of Dr. A. H. S —a son.

MARRIAGES

BINNS—WHITAKER.—On Sept. 17, at Ewell, Surrey, Geo Augustus Binns, M.R.C.S., surgeon lieut.-commander, to Joan Whitaker.

BREARLEY—HEWITT.—On Sept. 8, at Sandiway, Cheshire, Ro Brearley, M.B., to Joyce Mary Hewitt.

GARDNER—HARROWER.—On Sept. 29, in Edinburgh, Da Lindsay Gardner, M.B., to Helen Margaret Harrower.

RIGG—WALLACE.—On Sept. 29, in Glasgow, Charles Dick R M.B., to Vera Shaw Wallace, M.A.

WALTER—KELLY.—On Sept. 8, in Belfast, Major Roger P. Walter to Nora Kelly, M.B.

WEBBER—HAY.—On Sept. 28, at March, George Edward Fr Webber to Hilda Russell Hay, M.B.

DEATHS

FREEMAN.—On Sept. 29, Harry Freeman, F.R.C.S.

HOFFMAN.—On Sept. 26, at Cranham, Glos, Geoffrey Art Hoffman, B.A., M.B. Dubl.

JOHNS.—On Sept. 27, at Adderbury, Archibald Tisdall Johns, M.D. Dubl., aged 77.

MILNE.—On Sept. 29, at Aldeburgh, Suffolk, Robert Milne, M.S. Lond., F.R.C.S.

OME INTERPERSONAL FACTORS IN ILLNESS

F. R. C. CASSON
M.B. Lond., D.P.M.
IAL ASSISTANT IN DEPARTMENT OF PSYCHIATRY, NATIONAL HOSPITAL, QUEEN SQUARE, LONDON

E purpose of this paper is to draw attention to certain iological reactions which occur between the sick n and his human environment. Some of these are obvious, others more obscure, but nearly all are iciently recognised.

in all reactions, physical or psychological, both gents" are affected and mutually interactive. The nt's human environment, moreover, is composed number of persons—such as doctor, nurse, relatives, ellow patients—all of whom may react not only on but upon each other in relation to him. For sim- y's sake, the members of this environment will be dered as being isolated from one another but paired the patient, one by one, in a series of equations een the terms of which we must visualise the ⇌.

e practical effects of the various reactions are of more rtance to the patient, for they affect his recovery ven his survival; so his side of the equation will in case be considered first.

REGRESSION

illness, various degrees of regression to the depen- e and inadequacy of childhood take place. Sick le tend, physically, to be weak, unable to look after selves, needing to be nursed in bed, fed, and washed thers; mentally, they show the egoism of a child, "childishly" demanding, live very much in the ent, and are uninterested in their surroundings pt in relation to their own needs. As Hazlitt says, other things but our disorder and its cure seem less nothing and vanity."

his childish status is implied in the way the patient ually treated. He is subjected, especially in hospital, ll sorts of petty rules and restrictions; his general vities, his diet, sleep, and habits are supervised; loctor, in most cases, does not tell him what is wrong t him; his nurse bosses him about or insists on g everything for him; his relatives take over his onsibilities.

PATIENT ⇌ DOCTOR

"All patients, when ill, regress in some degree to infantile titudes, placing the physician in the position of parent nurse, from whom the utmost of care is demanded, t whom, on the other hand, it is very amusing to trick annoy" (Dunbar 1943).

he doctor, as the person who assumes responsibility the patient's cure, steps into a parental rôle, usually t of the father, and is unconsciously regarded as such the patient. The emotions felt by the patient for his father may be highly ambivalent, in which case doctor is regarded on the one hand with admiration, st, and affection, as a good omnipotent father who heal him, and on the other with fear and hatred, as ad punitive father who will castrate or kill. These ings derive from the Œdipus situation, and will vary their quality and intensity according to how far the ent has solved his original Œdipus problems in past.

he positive feelings towards the doctor have long been ognised, and are gratefully accepted and exploited gitimately so) by every doctor. The negative ones are s obvious. The patient tends to repress them because their original relevance; they are unwelcome to the ctor, who may therefore ignore them or ascribe them the whims and caprices of the invalid.

That the idea of the doctor as a malevolent figure is widespread may be inferred from the awe in which many primitive tribes hold their witch-doctor or medicine-man, and from the frequent occurrence of this theme in fiction and the fantasy-world of the cinema. In the classical instance of Dr. Jekyll and Mr. Hyde the two aspects of the doctor are combined in one person; and in Dr. Moreau, Dr. Mabuse, and many Boris Karloff rôles the doctor is represented as a mad, crafty, and criminal type.

Common parlance betrays the persistence of this idea; we still speak of food or drink as being "doctored" when we mean poisoned or tampered with, and a castrated tom cat is referred to as being "doctored." Among the working-class, it is not uncommon for children to be quietened by the threat: "I'll fetch the doctor to you!" and the belief that doctors only "experiment" upon their hospital patients is often voiced. Among all classes, the physician is accused of letting his patients die, the psychiatrist of hypnotising them, and the surgeon of cutting them up.

The surgeon naturally becomes the object of negative feelings more easily than other doctors, for he usually cuts or removes parts of the body and can therefore be viewed as *causing* pain by his procedures. His contact with the patient may also be too brief or urgent to enable positive feelings to be built up. He is usually less interested in his patients as individuals than is the physician, partly because his interest and skill lie to a large extent in technique, and also because much of his work is repetitive and impersonal—tonsillectomies, appendicectomies, herniotomies—and mainly of interest to him *en masse* or statistically. He would do well to remember that to the individual patient statistics mean nothing, save in so far as they serve to reassure him about his chances of benefiting from a particular operation, and that hardly any operation is classified as "minor" by the person undergoing it. John Smith's tonsillectomy is, to him, not only a major operation but a unique one.

Ambivalent feelings are also shown by an exaggerated belief in doctors, which credits them with almost superhuman knowledge and skill, coexisting with contempt and resentment for their failure to cure various illnesses; cancer and the common cold are familiar instances quoted by the layman. The unconscious inference is that since the doctor *can* cure anything, his not doing so is proof of his malevolence. This line of emotional reasoning reminds one of primitive peoples who invest their medicine-man with supernatural powers—such as the power to make rain—and indignantly depose or slay him when he fails to avert a drought, and of those "rationalists" who reject belief in God because He "allows" human suffering and war.

Any institution or individual possessing power or knowledge above the average (such as the Government, lawyers, scientists, "experts," and so forth) is liable to become the object of such ambivalence, but the doctor even more so, because he is concerned with persons who are ill and therefore more prone to be influenced by infantile modes of thought.

In this infantile situation, the patient may regard illness in two ways: first, as a threat to survival, to be combated with all his life-instincts, with the doctor as an ally; secondly, as a solution of, or means of escape from, life's problems, even to the point of actually dying. From this latter point of view the doctor is a stern unwelcome mentor who tries to make the patient abandon the "easy way out" and urges him to take up the burden of responsibility once more. From this point of view, too, the patient may gain his ends if he lives to "enjoy ill health," or has perpetual recurrences of his complaint (note the complacent way in which he will say "My chest has *always* been my weak spot, doctor!"), or dies without adequate physical pathological cause.

Society for the Study of Addiction

Prof. F. L. Golla will give his presidential address to this society on Tuesday, Oct. 18, at 4 P.M., at 11, Chandos Street, London, W.1. He is to speak on Problems for Research in *the Study of Addiction.*

B.C.G. Vaccine for Britain

A consignment of B.C.G. vaccine from Copenhagen reached London by air last Monday. Part went to the Children's Hospital, Sheffield, for vaccination of volunteers among the staff.

Manufacture of Streptomycin

Streptomycin can now be manufactured for sale in the United Kingdom only under licence, and it must conform with prescribed conditions as to strength, quality, and purity. These requirements are laid down in the Therapeutic Substances Amendment Regulations, 1949, under which streptomycin is added to the schedule to the Therapeutic Substances Act, 1925, as being a substance the purity or potency of which cannot be adequately tested by chemical means.

National Hospital, Queen Square, London

Today, Friday, Oct. 7, Dr. Wilder Penfield, F.R.S., director of the Montreal Neurological Institute, will speak on Observations on the Anatomy of Memory. On Monday, Oct. 10, Dr. Foster Kennedy (New York) will speak on Allergic Manifestations in the Nervous System, and on Thursday, Oct. 13, Prof. G. H. Monrad-Krohn (Oslo) on Diagnostic Errors in Neurological Practice. All three lectures will be held in the institute of neurology at the hospital at 5 P.M.

British Trust for Social Studies

This trust, to encourage social research of scientific and practical importance, offers small grants to free-lance investigators who are well placed for social observation but who would have to work up the material in their spare time: for example, a colliery manager, a probation officer, a hospital almoner, a shop steward, the warden of a hostel, the editor of a local newspaper. Application forms may be obtained, by post only, from Miss Marion Nuttall, secretary of the trust, 16, Queen Anne's Gate, London, S.W.1.

Middlesex Hospital Dinner

Presiding over the annual dinner of the Middlesex Hospital Medical School on Sept. 30, Prof. E. C. Dodds, F.R.S., spoke with deep regret of the recent death of Mr. Turner Warwick at the height of his influence in the hospital. He described the school as the most remarkable in London, because the founders had tried to keep the students' education on scientific lines as broad as possible. The tradition founded by Bell had been continued by Bland-Sutton (who indicated that Middlesex should be a school of research besides being a school for training doctors) and by Webb-Johnson; and he himself was eternally grateful that, with his colleagues, he had been allowed to develop the Courtauld Institute of Biochemistry without any apparent tie-up with medicine. Professor Dodds also spoke wistfully of the good old days when there was no limit to the number of times one could take the 1st, 2nd, or final M.B., and when discerning parents, for a composition fee of £150, could cover their sons' tuition for as many years as might be necessary. After his tenth year the senior student had become quite an important person; and the 1916 entry, to which Professor Dodds belonged, was distinguished in having contained probably the most senior student of all time, who retained his status till 1935.

Dr. H. E. A. Boldero, the dean, said that the past year, though it had seen the birth of the National Health Service and the separation of school from hospital under a new charter, had been satisfactorily uneventful. He paid warm tributes, of different kinds, to Prof. John Kirk, retiring from the chair of anatomy; to Mr. R. A. Foley, succeeded as secretary of the school by Miss Eileen Walton; and to Dr. William Sladen, decorated for his courage and fortitude in hazardous circumstances when isolated in Graham Land as medical officer to the Falkland Islands Dependencies survey. Dr. R. T. Turner Warwick, senior Broderip scholar, spoke of sporting events rather than the traditional complaints. Dr. G. E. Beaumont, proposing The Chairman, said that Professor Dodds owed his success to a curious combination of concentration and contemplation, which had enabled him, for example, to discover the new star Stilbœstrol. The Medical Research Council had been able to point to stilbœstrol as justifying all the money they had spent on medical research: and at one time it had even been hoped that it would close the dollar gap.

North of England Otolaryngological Society

The annual meeting of this society will be held Harrogate and District General Hospital, K[illegible] Road, Harrogate, on Saturday, Oct. 15, at 2 P.M.

General Board of Control for Scotland

The Secretary of State for Scotland has appoint Catherine Begg to be a deputy commissioner of the Dr. Begg, who graduated M.B. at Glasgow University is at present senior medical officer at Stoneyetts *Hospital, Chryston, Glasgow.*

Welsh National School of Medicine

Dr. F. R. G. Heaf has been appointed to the [illegible] professorship of tuberculosis.

Dr. Heaf took the Conjoint qualification from St. T Hospital in 1918, and, after holding various house- there, his M.B.Lond. two years later. His earlier pape Trachea in Tuberculosis and on Sanocrysin Treatment monary Tuberculosis reflect his interests during the of his career [illegible] Sanatorium, [illegible] Last year he [illegible] *in Respiratory Tuberculosis* and [illegible] o Papworth Village Sett [illegible] honorary consulting medical [illegible] With his appointment to the [illegible] ith the London County [illegible] adviser in tuberculosis to the Ministry of Health, the focu [illegible] and his later papers de [illegible] ous and with social asp [illegible] of the Tuberculosis As [illegible] *Education* Institute.

King's College Hospital Dinner

At the annual dinner on Oct. 1, Dr. Wilfrid Oakley pr the Medical School, which, he said, had always done to give students clinical experience, which was not th thing as the shifting dullness of the ward round. The had a certain touch of unconventionality, and liberty very spirit of progress. Mr. Harold Edwards, the said that last year some 900 students applied for 50 The final selection was made by personal intervie though it was distressing to reject the son or daug an old King's man, he felt sure that all would prefe children to get their place in the same way as anyo Negotiations were continuing hopefully for acqui additional hospital beds absolutely necessary for the d ment of the school. Dr. Sydney Thomson said that and hospital were living very happily together, officially living in sin. Sir Hugh Cairns had found at fine students, a happy atmosphere, and the faint t arrogance which he considered healthy and "which sure endears you to all the other London schools." He that in the National Health Service doctors would ta to guard their professional freedom—to be outspoke he thought that all should fight to preserve the pos the general practitioner, to which perhaps not enough tion had been paid so far. Dr. Terence East proposi health of The Chairman, Dr. J. H. Sheldon of W hampton, referred to his inquiries into bone diseases, a nervosa, hæmochromatosis, and latterly old age, and his naval service, his mountaineering, his cycling, a ornithology. Dr. Sheldon, in reply, remarked that had early discovered that in times of financial str exports were the thing to go for. He had exported hi Wolverhampton, and he strongly believed that this of export from London should continue.

Colonel M. Stoddart-Scott, M.P., has been elected ch of the British Rheumatic Association in succession to Dr. F. Hernaman-Johnson.

CORRIGENDUM: *Vitamin E.*—In line 6 of Dr. F letter of Sept. 24 *(p. 579)* the amount of ergotamine should have been printed as 50 mg., not as 5 mg.

ity to make the nurse feel herself part of an active espondent team. It is probable, however, that some es unconsciously resent having to spend their lives ng for other people's old folk when, by their ession, they have freed themselves from economic endence upon their own parents and are possibly ributing to their upkeep.

PATIENT ⇌ PATIENT

his relationship hardly arises in patients treated in r own homes, in the private wards of hospitals or ing-homes, or in consulting-rooms, but in those ted in general hospital wards or outpatient depart-ts it deserves consideration.

group of patients in a ward under the care of the same tors and nurses, or attending the same outpatient ic, reproduces the emotional situations in a family hildren. Just as children compete among themselves parental affection, so do patients for the attention of tor or nurse. There is jealousy for "sister's pet" or the patient with whom the ward doctor spends more e. There are rivalries and resentments, not always onal: the patient who coughs or groans all night nderstandably somewhat unpopular, but the noisy valescent is more keenly resented, because he is also ied.

ivalry in getting better is a real and helpful factor, parable to children's rivalry in growing up. The valescent "up-patient" in a ward has a sense of sure, very often, in doing things for his fellow ients for he can thus feel himself identified with the ing parent figures of the therapeutic team and at the e time show himself superior and good to the other ients, like an older child caring for the younger ones.

entification with other patients plays a very impor-t part in ward or clinic morale; it is usually based on ering from the same illness, but other factors such age and educational or social status come into play. en patients with the same complaint get together y voice their anxieties far more freely than they do the doctor; if they learn that a fellow patient has an operation or investigation which they expect to ergo themselves they eagerly cross-question him for the details of the experience. They obviously derive ch more reassurance from somebody of the same lay us who has "been through it himself" than they from the sometimes perfunctory reassurance of the tor.

lass or group therapy for patients with organic ease has been favourably reported on (Pratt 1908, 2, Buck 1937, Chappell et al. 1937). With an ormed medical chairman such groups may well derive efit from inter-sibling identifications and parental roval simultaneously.

f one listens to the conversations of patients together, is possible to notice a difference between those of ple with the same illness and those of people with similar illnesses. In the former, much more interest hown by the listener, who is given an attentive hearing return; in the latter, each party to the conversation ms only to be listening for a break in the other's nologue to talk of his own symptoms, and the com-nts of the listener show much less sympathy or insight.

The advantages of nursing similar cases in the same rd and of retaining the usual haphazard assortment at occurs in most medical wards have not, so far as I ow, been compared from this point of view. It may be ught that patients all suffering from the same serious ess would become depressed if nursed together, but s does not seem to happen in tuberculosis sanatoria.

The tendency of birds of a feather to flock together ay be of some use diagnostically in patients suffering m mental disorders. In wards filled with a mixed population of neurotic and psychopathic soldiers, I found that the psychopaths tended either to remain solitary or to "gang up" in fairly large but unstable groups, while the neurotics usually went about in twos and threes. A colleague who works in an observation unit has remarked to me on the tendency of patients suffering from organic psychoses, and of psychopaths, to seek out any of their fellows admitted to the unit.

PATIENT ⇌ FAMILY

Even the healthy person is apt to behave in a childish and uninhibited manner when at home; and the full extent of the sick person's psychological regression is most clearly seen in his home setting. The well-adjusted man will feel concern about his enforced inactivity in so far as it throws an additional burden upon his family and prevents him from giving his usual support, but this will largely reinforce his determination to get well quickly. The obsessional or depressed person may worry unduly about the trouble he is causing, and may become severely depressed, even suicidal, for his inactivity deprives him of his usual defensive behaviour in the shape of over-conscientiousness or unremitting work.

It is generally realised that the element of "secondary gain" to the patient arises in functional illness, but an organic illness affords him similar opportunities. The neurotic or immature person will exploit his illness, more or less unconsciously, to secure a larger share of love and attention from parents, spouse, or children, to return to a state of infantile dependence, to dominate the family, to revenge past neglect, real or imaginary, and to escape various responsibilities. It is for instance a common excuse of neurotic patients, when asked why they have no family after several years of marriage, to reply that they are waiting until they feel well themselves. In other cases the same reluctance is expressed in the form of impotence or frigidity, by the asthma of the married woman which comes on at night and prevents marital relations, or the hyperemesis gravidarum that results in termination of the unwanted pregnancy.

Illnesses which "run in the family" are no doubt often due to genetic, infective, and environmental factors, but the patient's identification with someone in the family, or with a friend or workmate, may play a decisive rôle; Dunbar (1943) has drawn attention to the importance of this "exposure to illness" in the case of psychosomatic disorders.

A young soldier who complained of attacks of dyspnœa and pain in the chest and who thought he was getting "asthma" gave a vague family history of "heart trouble." Detailed discussion of the death of his favourite brother (regarding which he had severe feelings of guilt, ostensibly attributed to some minor negligence) revealed that this brother had complained of similar symptoms just before his death; and the realisation of this produced an immediate improvement.

FAMILY ⇌ PATIENT

The sick man's family usually have mixed feelings towards him. Love, pity, and solicitude will be more in evidence, owing to their social acceptability; they will often be exaggerated when there is a good deal of underlying hostility or resentment to cover up, or when there is a desire to dominate the patient and keep him in a dependent status. When hostile feelings are permitted expression it is usually in some such phrase as "Well, she never *would* eat proper meals," "He doesn't seem to do all he might to help himself," or in remarks of the "He-never-would-take-*my*-advice" variety.

Resentment may be displaced on to the doctor, hospital, employer, or Service, the relatives accusing them of having caused or having failed to cure the illness. In ex-Service cases, they often complain that the patient should never have been called up, should have been treated with more consideration, should have been dis-

The advantage to a patient of having positive feelings for his doctor is indubitably great. One of the lessons of history is that most men dislike responsibility, even when healthy: it is still less welcome to the sick. The patient's most acute need is for someone who will take the load off his shoulders, and in this regard the greater his faith in his doctor the better. To disabuse a man of excessive faith in his doctor is seldom right and almost never beneficial unless he is to change to another doctor forthwith. To believe that a good "father-figure" is looking after him is of the greatest help to the sick man; he is able to feel "good" because he can "love" the doctor, and he is further reassured of his own goodness because he feels that the doctor "loves" him. In this way he can emulate the small boy who has grown successfully through the Œdipus situation to love and be loved by his father, and with him as guide and example go forward into manhood.

DOCTOR ⇌ PATIENT

In handling the patient, many doctors rely on the maxim "Nothing succeeds like success," but the obverse of this is "Failure is fatal." The doctor must decide whether he shall tacitly accept the rôle of omnipotence for which he is cast by the patient, or endeavour to be plain and straightforward. He will probably be wise to accept his patient's confidence, remind himself constantly that it is somewhat exaggerated, and at the same time buttress it by explaining as far as possible what he is doing; by the latter procedure he will, incidentally, safeguard himself to some extent when things go wrong.

For a patient with decided negative feelings towards him, the best of doctors may be able to do nothing. Probably he can best deal with such a patient by his acceptance of the possibility of such feelings; for if he is alive to their presence he will be able to devote more effort to reassuring the patient, making him feel that his case is being given due consideration, and endeavouring to encourage positive feelings. To tolerate the patient's hostility—disguised and rationalised as it may be in various ways, such as disobedience to orders about diet, forgetfulness about taking medicine or keeping appointments, and excessive querulousness—and to make the patient realise that he has a doctor who can tolerate all this may well be the most effective form of reassurance.

The value to the doctor of his patients is not sufficiently realised. The average doctor (as distinct from the more commercially minded, and those who have found their niche in medicine in one of its more impersonal fields, such as pathology or bacteriology) finds a large part of his reward in a sense of beneficent power in being useful to his fellow men. If his personal life is unsatisfactory he may tend to treat his patients as his children or younger brothers, try to influence them unduly, fuss over them, and over-protect them, with the risk of eventually becoming embittered when they resent his authority and neglect his advice. He may also condemn in his patients what his conscience does not allow in himself, and this moral severity may cloak itself as professional solicitude. For instance, the doctor may forbid alcohol or tobacco, restrict diet, or prescribe painful treatments or unpleasant medicines to a degree not warranted by the patient's condition, withal in perfect good faith.

The doctor who is anxious or obsessional may become unduly perfectionistic and wear himself out with overwork in the service of his patients. I remember acting as locum tenens for a general practitioner who was so anxious about all his patients that he hovered around the practice, delaying his family from starting on their holidays, for three days.

Reluctance to admit to himself that his patient can do without him leads many a doctor to be over-protective and to prolong the period of the patient's dependence upon him. The psychiatrist is one of the worst in this respect. Admittedly there are those will never be able to stand alone, but many encouraged or allowed to become perennial of the "supportive clinic." Follow-up clinics sorts, which keep the patient more or less under the wing of the hospital, are not immune same disadvantage.

PATIENT ⇌ NURSE

The patient's feelings towards the nurse are akin to those felt for a mother or sister, and vary a deal between male and female patients. Women are usually more critical, demanding, and the nurse's authority, though some men will the nurse their resentment of a domineering or possessive mother or wife. Overt sexual feelings their nurses by men patients are fairly convalescence, but in the severer stages of illness, the accompanying psychological regression, ings are in abeyance, or have regressed to the love-object, the patient's own body. Moreover, nurse's rôle as a mother-surrogate, who tends the man more or less as his mother did when he was an in desexualises his conscious feelings towards her, an therefore thinks of her as a sexless angel.

Adolescent girls may develop a crush on the when convalescent, but for most women patien sense of identification with the nurse is more impor based on earlier identification with their mothers. are ready to accept unquestioningly her pronouncem on medical matters, especially those connected obstetrics or the rearing of children. Certain man turers of infant foods and gripe-water have recog this fact, illustrating their advertisements with picture of a motherly looking nurse.

NURSE ⇌ PATIENT

It is generally recognised that the nurse finds an for her "maternal feelings" in caring for the sick; is probably a true enough approximation, though undoubted pleasure that many male nurses derive similar work shows that tender protective feelings not the monopoly of one sex. These feelings have origin in the nurse's unconscious identification wit or her own mother, or ideal mother image, on the hand, and with the patient on the other, so that loo after the patient as she would have wished her fant perfect mother to look after her becomes a so valuable form of self-gratification. Just as a m may indulge her maternal feelings at the expense o child's independence, so a nurse may unwisely spoi over-protect her patient. The good nurse const encourages him, so far as his physical condition per to regain his self-reliance, and, in both senses o phrase, to stand on his own feet as soon as possib

It is noticeable that most nurses prefer what one call the material services, such as bed-making, banda giving medicines, and generally "making the pa comfortable" physically, to the intangible but eq important service of talking in a cheerful and reass manner to their charges. In a military hospital fo treatment of neurotic soldiers where I worked, it difficult at first for the nursing officers to grasp how could help in the treatment of patients who were m up and about. To begin with they could find littl do beyond checking the ward stores and serving m but as they gained insight and interest they bec invaluable helpers.

Nurses are often unwilling to work in chronic w for the aged sick. Realising that these old patients sel make a lasting recovery, they become discouraged feel that their labours are in vain. Such an atti reflects on the keen [illegible] of the medical staff and on t s was as follows: over nine years, 4 cases; over t years, 10 cases; over seven years, 14 cases; over years. 21 cases: over five years. 33 cases; over four s, 51 cases; over three years, 70 cases; over two s, 91 cases; and over one and a half years, 104 s.

ight patients died within eighteen months of their examination.

hese results will not surprise any surgeon who has wed the progress of patients treated by perurethral tatic resection. In the modern forms of this operation e quantities of tissue are removed and the surgeon to resect the entire hypertrophied portion. He is kely to succeed in doing so except in a very few s. Yet recurrent obstruction is uncommon. I wed up 273 cases of benign hypertrophy of the dular type treated in this way. Regrowth of gn tissue or development of malignant disease of prostate caused recurrent obstruction in 13 cases. 260 cases where obstruction had not occurred ite the almost certain presence of hypertrophied tatic tissue were followed up for the following ods: over ten years, 9 cases; over nine years, 20 s; over eight years, 29 cases; over seven years, cases; over six years, 69 cases; over five years, 91 s: over four years, 117 cases; over three years, cases; over two years, 206 cases: over one year, cases; and less than one year, 21 cases.

here is no theoretical reason why prostatic obstruction uld be invariably progressive. Its cause is believed to disorder of involution. Normal involution is a process imited duration, and it is reasonable to suppose that ormal involution will be likewise. Also prostatic truction is related to the form and not to the size the gland; increase in size does not necessarily mean rease in obstruction.

DEATHS

f the 129 patients treated expectantly, 18 died. e causes of death, as given by their doctors, were: tour of lung (3), carcinoma of stomach (2), cerebral morrhage (2), cardiovascular disease (2), cardiac ure (2), coronary thrombosis (2). pneumonia (2), eral senile changes (1), malignant disease of testicle and uræmia (1). The patient who died of uræmia aged 91, and with the possible exception of this case s unlikely that the prostate was responsible for any these deaths. However, the possibility that the state played a contributory part must be considered. e figures after the questionary of November, 1947, re submitted to Dr. R. A. Robb, lecturer in statistics the University of Glasgow. I asked for a comparison tween the rate of survival in these cases and the pected rate of survival of men of the same ages followed ing the same periods. Dr. Robb found "no significant ference between observed and standard probabilities surviving." It may therefore be assumed that the sence of prostatic enlargement did not affect the ation of the lives of these patients.

PROGRESSIVE CASES

n the group of 129 cases, 17 have been operated on ter a period of expectant treatment; 4 of these onged to the group of 15 in which expectant treatment as advised because of special circumstances despite e fact that the case did not conform to the general ndards adopted. In these 4 patients operation was vised because of persistence or recurrence of symptoms. wo of them had had acute retention. and repeated tacks occurred. One very frail patient had extreme iculty in micturition, requiring a very long time to pty the bladder; expectant treatment was advised ause symptoms appeared to be decreasing. but after some months they became more severe and operation was advised. The fourth patient had a residual urine of 6 oz. at his first visit, but he was obviously a very nervous man, and the accuracy of this estimation was doubted; he was seen at intervals for about a year, and similar quantities were found on several occasions; operation was advised.

PROGRESSIVE CASES

Case no.	Age (yr.)	Degree of enlargement	Difficulty	Hesitancy	Frequency (day/night)	Hæmaturia
1	57	Slight	Moderate	Not recorded	Variable. Sometimes extreme	None
2	56	Gross	None	Slight	3–4 hrly. 0–1 times	Present
3	55	Moderate	Moderate	Moderate	2 hrly. 1–6 times	Present
4	55	Moderate	Moderate	None	4 hrly. 1–2 times	None
5	58	Considerable	Slight	Slight	2–3 hrly. 3–4 times	None
6	60	Considerable	Slight	Slight	2 hrly. 3–4 times	None
7	55	Considerable	Moderate	Moderate	1½ hrly. 1–2 times	None
8	56	Moderate	Moderate	Moderate	3–4 hrly. Twice	None
9	66	Slight	Slight	None	2 hrly. Once	Present

Of the 114 patients whose clinical condition conformed to the general standard adopted, I operated on 9. In 1 of these the indication was gross hæmorrhage, and there was no indication of increasing obstruction during six and a half years. In the remaining 8 patients obstruction had increased, and these may be described as progressive cases. Of the 4 patients treated by other surgeons, 1 is known to have had increasing obstruction and may also be called a progressive case. These 9 progressive cases are worthy of special study in an endeavour to identify common clinical features. The accompanying table gives some details about these patients at the time of their first examination.

AGE

The ages of the entire series were as follows: under 40, 1 case; 41–50, 5 cases; 51–60, 45 cases; 61–70, 55 cases; 71–80, 20 cases; 81–90, 2 cases; and over 90, 1 case.

Of 78 patients over the age of 60 only 1 showed definite evidence of increasing obstruction. Benign prostatic enlargement is believed to be a disorder of involution. Moore (1936), who studied the normal involution, states: "It would appear that the involution proceeds with greater rapidity during the fifth and sixth decades and that after 60 years the changes are less striking and the velocity greatly decreased." Moore (1943) has also studied benign hypertrophy and formed the opinion that "the ætiological agent is present during presenility and senility but is most active during presenility." This view is strongly supported by the present investigation.

SIZE OF THE GLAND

The enlargement was recorded as slight in 15 cases, moderate in 75 cases, considerable in 32 cases, and gross in 7 cases. The common feature of these cases was the mild degree of obstruction, though all degrees of enlargement were found. It has long been known that obstruction is related to the form and not to the size of the gland. The table shows that size is not even important in the assessment of prognosis. Two of the patients with the largest prostates in the series have been followed for about eight and a half years. Their symptoms remain mild. and recent estimations of residual urine showed an ounce in one case and less than an ounce in the other.

charged from the Service sooner, and should have been given a pension, or a larger pension. These complaints are usually voiced as being motivated solely by concern for the patient's well-being, but the underlying resentment of him, viewed as an investment which not only is paying no dividends but is entailing a loss, is often betrayed by the remark that *they* cannot afford to keep him.

Factors such as economic difficulty, the inconvenience and labour involved in housing and nursing the patient at home, or making long tedious journeys to visit him in hospital cause a natural resentment of his demands. Also his family are often hurt by his ingratitude or petulance, and may use these to justify their own lack of sympathy towards him. On the other hand, he may become the object of coddling and over-solicitude on the part of mother or spouse or other members of his family, and if he has an undue tendency to regress to infantile dependence this oversympathetic atmosphere will encourage it.

SUMMARY

1. The sick person shows psychological regression in greater or less degree.
2. His reactions to doctor, nurse, fellow patients, and family are largely due to unconscious factors derived from early life.
3. The effects of these unconscious factors, and of his regression, on the relations between him and the people in his immediate environment are discussed as a series of reciprocal interactions.

EXPECTANT TREATMENT OF BENIGN PROSTATIC ENLARGEMENT

T. L. Chapman

UROLOGICAL SURGEON, VICTORIA INFIRMARY, GLASGOW,
HAIRMYRES HOSPITAL, LANARKSHIRE, AND BALLOCHMYLE
HOSPITAL, AYRSHIRE

Some surgeons perform prostatectomy on all patients referred to them with prostatic enlargement and urinary symptoms, their aim being to eliminate so far as possible the advanced "bad risk" case. On the other hand, some general practitioners do not refer prostate cases to the surgeon until they have reached this advanced stage. These practitioners may have followed for many years men with enlarged prostates whose symptoms were only a minor inconvenience and whose health was never affected by the prostate; they fear that a major operation may be advised for a harmless condition. Clearly, sound judgment lies between these extreme views.

PRESENT INVESTIGATION

My practice is to advise expectant treatment in about 20% of all cases of benign prostatic enlargement referred to hospital or seen in private consultation. In general expectant treatment is advised when (1) residual urine is absent or small in amount, (2) difficulty in micturition is absent or slight, and (3) there have been no attacks of acute retention. These conditions were fulfilled in 114 of the series of 129 patients discussed in the present investigation. Such patients sought advice chiefly because of frequent or hesitant micturition or hæmaturia.

Five patients with residual urine of over 6 oz., 1 patient with extreme difficulty in micturition, and 9 patients who had had attacks of acute retention were also treated expectantly, either because they were considered to be bad risks for operation or bec they were very reluctant to be operated on.

The advice given was simple and was meant to prev prostatic congestion. The patients were warned of danger of chills, alcoholic excess, and failure to d the urge to empty the bladder. They were advised report any increase in urinary symptoms or any evide of failing health, but it was suggested that no such was likely to happen. I tried to assess the psych reaction of the patient and to vary the advice so to avoid both morbid introspection and danger complacency.

Records of these cases have been kept since the of 1938. Information obtained at return visits, the patients' doctors, and in some cases from the friends is collected. Postal questionaries are sent patients who have not been seen for a time and whom doubt is felt. In addition all patients were questionaries in December, 1944, April, 1946, 1947, and January, 1949. When question forms returned by the post office an almoner visited district and usually succeeded in discovering the address. When no reply was received an almoner visited, and in most cases a reply was obtained. W the answers to the questions showed an increase symptoms, another examination was arranged. Wh information was received of a patient's death, lett were sent to his relations and to his doctor asking abo the cause of death and whether there had been a increase in urinary symptoms. During the last y invitations have been sent to all survivors asking th to attend for examination.

In the present survey all patients seen for the time during the last eighteen months and 2 who were untraced after the first visit are exclud but 8 patients who were followed for several yea but have been untraced recently are included. T series contains 129 cases of benign prostatic enlargeme where expectant treatment was advised. This includ all such cases referred to the urological clinic of t Victoria Infirmary or in private practice during th period. It does not include: (1) patients admitt with very advanced disease where treatment wou have been advised but for the moribund or almo moribund state; (2) patients with very slight enlarg ment both on rectal and endoscopic examination; a (3) cases in which firm areas were felt which sugge malignant change—these last were given the bene of endocrine therapy.

Cystoscopic and urethroscopic examinations have n been performed when the diagnosis could be establish by other means. Following the advice of Macalpi (1936) and others I reserved these methods chiefly f cases where hæmaturia had occurred or where t enlargement felt per rectum was not definite.

GENERAL RESULTS

In 13 cases I considered operation necessary aft a period of observation. In 12 of these the indicatio was obstruction, while in the remaining case seve hæmorrhages from the prostate followed a marriage la in life.

Four patients have consulted other surgeons an undergone operations. In 2 of these the indications a not known. In 1 obstruction was increasing. Th remaining case, followed for four years, had no evidenc of obstruction. The second surgeon agreed that th condition was static but believed that progressiv changes would occur later; it was also hoped to reduc the frequency of micturition—a result which had no yet come about six months after operation.

In 112 patients there has been no evidence of increasin obstruction. The len of follow-up in these eigh as been seen several times since then and shows little e in his general and local condition.

FREQUENCY OF MICTURITION

e more serious cases usually have more frequent rition than the less serious ones:

Frequency	*500 cases recommended for operation*	*129 cases treated expectantly*
reme at night (4 times or ore)	252 (*50%*)	31 (*24%*)
reme by day (every 1½ urs or less)	189 (*38%*)	29 (*22·5%*)

equent micturition in prostatic enlargement may be o various causes. Where there is residual urine, the anism is obvious. If the bladder still contains urine micturition, a shorter period of secretion will be red to reach the state of distension which produces lesire to pass water. This effect, however, may be ed partially, and even completely, by a gradual ase in the capacity of the bladder. In the absence sidual urine other causes may be effective. Local estion may produce irritability of the trigone: unculated middle lobe of the prostate may produce same type of irritation as does a stone or foreign : the enlargement of the prostate may develop ich a way that the bladder neck is dilated but the into the prostatic urethra is not blocked; the walls he urethra may not be accurately opposed to one her and may meet only at the most prominent parts he prostatic lobes, allowing urine to pass into the itive prostatic urethra and produce irritability and tency; and hypertrophy of the detrusor may etimes reduce the capacity of the bladder.

he table and the figures given above for extreme uency show that only 4 of 31 cases where night uency was extreme, and only 2 of 29 where day uency was extreme, have had a progressive course. degree of frequency has no prognostic significance. uent micturition is important only when its degree persistence cause exhaustion or great mental distress.

HÆMATURIA

pontaneous hæmaturia is said to be most common patients with incomplete retention (Marion 1940, lker 1933). This has not been my experience. In cases where residual urine was absent or scanty re were 24 (19%) cases of hæmaturia, whereas in cases in most of which the residual urine was conrable there were 82 (16%) cases of hæmaturia.

æmorrhage from the prostate is not usually severe l only rarely is it necessary to operate to prevent ther loss of blood. I encountered 2 such cases in 500. n the group of cases treated expectantly 24 had maturia, but only 3 of these showed progressively reasing obstruction. Hæmaturia is therefore of no gnostic significance.

GENERAL COURSE OF CHIEF SYMPTOMS

Nine patients had had attacks of acute retention before ir first visit; 2 of these had repeated attacks later d were treated by operation, but the remaining 7 ve had no recurrence of acute retention. The follow-up these 7 cases has been as follows: over eight years, case; over seven years, 2 cases; over five years, cases; over four years, 5 cases; and over three ars, 6 cases.

Fifty-three patients had slight or moderate difficulty micturition: in 8 of these the difficulty increased ficiently for operation to be advised; in 11 difficulty ntinued to occur at times; and in 34 the difficulty had isappeared at the time of the next questionary and did ot recur during the period of observation. The periods hich have elapsed since the first examination in ese 34 cases are as follows: over nine years, 1 case; ver eight years, 2 cases; over seven years, 3 cases; ver six years, 5 cases; over five years, 10 cases; over four years, 16 cases; over three years, 19 cases; over two years, 26 cases; and under two years, 8 cases.

Frequent micturition was the commonest complaint at the time of the first examination: 93 patients were disturbed more than once each night and had intervals of two hours or less during the day. In most of these cases this symptom showed fluctuations, but in 34 of them there was considerable improvement at the time of the next questionary, and this improvement was maintained throughout the period of observation. The duration of the follow-up in these 34 cases was as follows: over nine years, 1 case; over eight years, 2 cases: over seven years, 6 cases; over six years, 10 cases; over five years, 15 cases; over four years, 22 cases; over three years, 24 cases; over two years, 29 cases; and under two years, 5 cases.

DISCUSSION

The size of the prostate is unrelated to the degree of obstruction which it produces. On this point there is wide agreement (Joly 1924, Marion 1940, Walker 1933, Lowsley and Kirwin 1944, Hinman 1935, Keyes and Ferguson 1936). Obstruction depends on the form of the gland. Many enlarged prostates do not obstruct, or obstruct so little that a slight hypertrophy of the detrusor is sufficient to empty the bladder. Such cases are recognised by the absence of difficulty in micturition and of residual urine. The present investigation suggests that the non-obstructive or very slightly obstructive prostate has a strong tendency to remain so.

Sudden changes in the effects of an enlarged prostate are due to changes in vascularity. If great obstruction is produced, the efforts of the bladder to empty itself will maintain the congestion. If only slight obstruction or mere irritation is produced, the congestion may disappear and remain absent for a long time. If during the interval there has been active growth, the obstruction produced by the second attack may be much greater than that produced by the first. If the period of active growth has passed, the second attack is likely to be no more serious than the first. The present investigation suggests that active growth in the prostate ceases soon after the age of 60. The general course of symptoms shows that potentially obstructive and potentially symptom-producing prostates very often lie dormant for many years. It is therefore not unreasonable to suppose that growth ceases or becomes very slow after the age of 60, though most patients seek advice after that age.

Patients seek advice during an exacerbation of symptoms. If a prostate in a congested phase produces only slight obstruction, and if that prostate has passed its period of active growth, it is unlikely ever to be a source of danger. The present investigation, however, included chiefly patients with little or no residual urine and no history of acute retention. If the bladder muscle has been overdistended, an additional factor is introduced. Recovery of muscle tone will be less complete in the older patients.

Three clinical types of prostatic enlargement are commonly described:

(1) Classical progressive type described by Guyon (1888). The patient passes through periods of congestion, of incomplete retention without distension, and of incomplete retention with distension.

(2) Sudden acute retention with little or no previous history of urinary symptoms.

(3) Silent prostatic obstruction. The bladder distends gradually without well-marked urinary symptoms, and the patient complains, first of all, of loss of weight and energy or of gastro-intestinal symptoms. Such cases are rare. Of 629 prostatic patients referred to me only 4 were of this type.

The present investigation suggests that a fourth clinical type, the non-progressive type, should be included.

URINARY OBSTRUCTION

When the prostate obstructs, the bladder muscle hypertrophies. Joly's (1924) theory is probably the best explanation of the mechanism of obstruction in these cases. According to this view the hypertrophy of the bladder muscle will be completely ineffective in the more obstructive type of gland. The greater the intravesical pressure in such cases the more firmly is the urethra closed. In the less obstructive types, however, hypertrophy of the bladder muscle can overcome the obstruction.

Trabeculation of the Bladder

The innermost coat of the bladder muscle is incomplete and is in the form of plexiform muscle strands. When the bladder hypertrophies, these strands become prominent and produce trabeculation. Hallé and Motz (1902) described these changes in three degrees: in (1) the spaces between the trabeculæ reach only to the next muscle layer, and there is hypertrophy without disturbance of the normal anatomical arrangement; in (2) the spaces extend through the middle and outer muscle coats and reach the fibroserous layer; and in (3) the mucosa herniates through the whole thickness of the bladder wall. Compensation is adequate in the first degree, is failing in the second, and has already failed in the third.

In the present series 56 patients were examined cystoscopically. Trabeculation was found in a large proportion, strongly marked trabeculation being recorded in 14. Of these only 1 is included in the progressive group. Four of them have been followed for about five years; 1 of these has noted lately a decrease in the force of the flow of urine; the 3 others have no difficulty in micturition. Recent estimations of residual urine showed $1^1/_2$ oz. in 1 case and smaller quantities in the 3 others.

Trabeculation of the bladder seems to be of little value as an indication for operation. Trabeculation with multiple sacculation is no doubt an indication, but in my experience this condition has always been associated with a significant quantity of residual urine. However, as pointed out by Millin (1947), the absence of trabeculation is a strong contra-indication to operation.

Difficulty in Micturition

Difficulty in micturition is described in several ways by prostatic patients. Commonly they have noted weakness and lack of projectile force in the flow of urine, especially at the end of micturition, when the flow may become a dribble. The protracted effort required to empty the bladder is also often described. When difficulty was great, I recommended operation even if the patient could empty his bladder. Of 114 patients with standard indications for expectant treatment, 53 had slight or moderate difficulty in micturition, and 8 of these have shown evidence of increasing obstruction. In 61 cases there was no complaint of difficulty, and only 1 of these has developed difficulty later. It therefore seems that the patient's description of micturition is of considerable help in prognosis.

However, some patients who have a significant quantity of residual urine do not complain of difficulty in micturition. I found 44 such cases in a series of 500 recommended for operation. These 44 patients included many of the most advanced cases. Owing to loss of tone the bladder was believed to be empty when a considerable quantity of urine remained. Many of them had a urinary stream which would not have satisfied a normal fit man, but other symptoms, such as frequency and urgency of micturition, were so prominent that the patient thought little of a gradual decrease in the projectile power of the bladder. Even in the absence of a residual-urine estimation such cases would not readily be confused with the mild type which is discussed here.

Hesitancy in Micturition

In the initiation of micturition the bladder neck opened chiefly by flattening of its lower segment. T is a different mechanism from the contraction of detrusor which empties the bladder. It is there not surprising that hesitancy and difficulty in mict tion are not invariably associated with one anoth Hesitancy seems likely to be the less signific symptom, and this is borne out by the present surv

Residual Urine

When the bladder muscle fails to overcome obst at its outlet, emptying becomes incomplete, and surgeons consider the amount of residual urine to a very significant indication of prognosis.

Danger to life occurs when the effects of pressure felt in the upper urinary tract. The mechanism of t is uncertain. If the valve action of the lower becomes incompetent owing to abnormal distension the bladder (Graves and Davidoff 1923), the amount residual urine may be considered an infallible gui If obstruction is produced in the lower ureter by overactive trigone (Young and Davis 1926) or by a hyp trophied detrusor (Kreutzmann 1928), the amount residual urine is a less reliable guide. The second vi is more probable, since cases are sometimes seen wh the upper urinary tract is dilated though there is residual urine. Millin (1947) points out this danger, b such cases are rare and unlikely to be missed if extre difficulty in micturition is considered seriously and if doubtful cases are examined by intravenous pyelograph

Fallacies in Estimation of Residual Urine

Several fallacies in the estimation of residual uri must be remembered. Kirwin and Hawes (1939) ha shown that a normal man who has retained his urine voluntary effort for an unusually long time may have considerable quantity of residual urine. This has obvio practical importance. Many patients with a urina complaint feel it their duty to come for advice wi a full bladder to provide a specimen. If a special effo of this kind has been made, the amount of resid *urine may be an unreliable guide.*

Many men have difficulty in micturition in the presen of others. It is useful to confirm the patient's descripti of the force of flow of his urine, but in many cases it advisable to allow the patient to pass urine alone so to obtain an accurate measure of the residual urine.

Infection reduces the amount of residual urine. the infection becomes chronic, the residual urine w never reach its former level (Ogier Ward 1943). Su changes must not be mistaken for improvement.

The amount of residual urine varies from day to da Too much reliance must not be placed on a sing estimation. If there is any doubt, the patient shou return for a second estimation.

Kirwin and Hawes (1939) have shown that a so rubber catheter empties the bladder less complete than does a cystoscope sheath. However, the differen was only 3–10 ml., a quantity unlikely to influence decision for or against operation. I use soft rubb catheters to reduce trauma to a minimum.

The small number of progressive cases in the presen series suggests that a low residual urine is a valuabl guide in the selection of cases for expectant treatmen I do not suggest, however, that the presence of more tha 4 oz. of residual urine is a certain indication of an earl downhill course.

A patient seen four years ago had over 6 oz. on tw occasions. Owing to an anginal attack a few months befor expectant treatment was advised. It has been impossib to see him again, but he reports improved health and le troublesome urinary symptoms.

A frail dyspnœic man of 87, seen for the first time two yea ago, had a bladder distended to the level of his umbilicus

EROYL-POLYGLUTAMIC ACIDS IN THE REATMENT OF PERNICIOUS ANÆMIA

HÆMATOLOGY IN THE UNIVERSITY

OLIC acid (pteroyl-γ-glutamic acid) was isolated from ral sources, such as green leaves and grasses, as well east, liver, kidney, and many other natural food-s. It normally occurs in food in the form of closely ted conjugated substances (Bird et al. 1945) which essentially polyglutamates—i.e., pteroyl-γ-glutamic combined, through the γ carbon atoms of the amic-acid molecules, with further numbers of amic-acid molecules, which can be broken down by me or bacterial action into the parent folic acid.

olic acid itself is almost universally active in relation acterial growth or the relief of certain deficiency rbances in human, animal, and chick anæmias or ral leucopenias, but the pteroyl-glutamic acid con-tes or polyglutamates have much more restricted ons until they have been hydrolysed.

wo naturally occurring crystalline polyglutamates e been isolated from different sources:

) Pteroyl-hepta-γ-glutamic acid (pteroyl-hexa-γ-glutamyl-mamic acid; the yeast-vitamin B_c conjugate), which was ted by Pfiffner et al. (1946) from yeast extracts and has effect on growth of *Lactobacillus casei* and *Streptococcus lis.*

) Pteroyl-tri-γ-glutamic acid (or pteroyl-di-γ-glutamyl-γ-amic acid; the "fermentation" or *L. casei* factor), pared by Hutchings et al. (1944) from certain coryne-ria residues, promotes growth of *L. casei* but has only the activity for *Strep. fæcalis.*

he remarkable therapeutic and hæmatological results ained with folic acid in the treatment of pernicious mia (see Wilkinson 1948) naturally suggested that c-acid deficiency played a part in the ætiology of this ase; consequently it was suggested by some workers t patients with pernicious anæmia were able to utilise y the parent folic acid and not the pteroyl-poly-tamates from which it is normally formed. In persons hout megaloblastic anæmia folic acid was thought by e to be liberated by the action of either the normal tric juices (hæmopoietin) or enzymes elaborated by, present in, the liver or elsewhere in the body (Bethell l. 1947, Heinle et al. 1946–47a and b). These observa-ts were based on definitely suboptimal doses of the ural conjugates; and, though the clinical details were convincing, Bethell et al. (1947) concluded that the ient with pernicious anæmia cannot utilise these jugates; the failure was not absolute and varied in erent patients, depending in part on the presence of onjugase-inhibiting substance in the extracts. Spies 47) claimed hæmatological responses in pernicious mia after using both natural and synthetic poly-tamates, including a diglutamate. Sharp and nder Heide (1947) showed that natural B_c conjugate eroyl-hepta-γ-glutamic acid) not only produced good missions in pernicious anæmia but also increased the nary excretion of pteroyl-γ-glutamic acid as in normal ople.

Jukes et al. (1947) observed that in normal people eroyl-tri- and di-glutamic acids were readily hydrolysed d excreted in the urine as folic acid, and Jukes and Stokstad (1948) noted that a patient with pernicious anæmia gave a submaximal response when given 3 mg. of pteroyl-tri-γ-glutamic acid daily intramuscularly for 11 days. In view of these conflicting reports, and the bearing of these results on the ætiology of pernicious anæmia, we have explored the situation further, using the synthetic polyglutamic acids.

MATERIALS AND METHOD

We used two of these synthetic folic acid conjugates: (1) pteroyl-tri-γ-glutamic acid (teropterin); and (2) pteroyl-di-α-glutamic acid (diopterin). They were provided as dry sterile powders, and for use by any route they were dissolved in appropriate volumes of a sterile phosphate buffer solution at pH 7·4.

Thirteen patients with pernicious anæmia were treated with these folic acid conjugates, eleven were new cases, and two had attended the clinic before and had relapsed because they had neglected treatment. All had achlorhydria and predominantly megaloblastic marrows with macrocytic anæmias at the time of the tests. All except case 7—a severely anæmic and ill patient—had been observed for at least a 7-day control period before any treatment was given, the reticulocyte-counts remaining low during that time. Eight patients were treated with

* Intramuscularly unless otherwise stated.

This group would include those patients who have no difficulty in micturition and no residual urine and those over the age of 65 who have slight difficulty. There were 85 such patients in the present series: 2 have shown evidence of increasing obstruction, 1 has had an operation by a surgeon whose precise standards are not known; and 82 have been observed for the following periods: over nine years, 4 cases; over eight years, 9 cases; over seven years, 12 cases; over six years, 19 cases; over five years, 25 cases; over four years, 39 cases; over three years, 50 cases; over two years, 68 cases; and under two years, 14 cases. These patients have shown no evidence of increasing obstruction. Recent residual-urine estimations in 41 of them have shown *insignificant quantities*.

Such cases probably exist in enormous numbers. In the past these patients accepted their symptoms as a natural result of their age, but with spreading knowledge more and more of them tend to seek advice. They might all be regarded as in the first stage of the classical progressive type, but the present study suggests that this is true only of a small minority. No clinical classification is precise, but the cases of the suggested non-progressive type have been sufficiently consistent in their course to justify grouping them together for practical purposes.

Non-progressive cases are described by many workers but usually as rare exceptions. The published reports abound in question-begging terms. Mild prostatic obstruction is called an "early prostate." Expectant treatment is described as "postponing" operation. These might be added to the "witch words" of Sir Alan Herbert (Herbert 1935).

In selecting cases for operation, difficulty in micturition, residual urine, and age are important, and frequency of micturition, the size of the gland, hæmaturia, and trabeculation of the bladder are not significant. It is suggested that patients whose difficulty in micturition is not great and who have little or no residual urine should be treated expectantly. Slight difficulty in micturition should be considered more significant in patients under the age of 60 than in older patients. Severe hæmaturia is an indication for operation in exceptional cases. Persistent extreme frequency of micturition may cause exhaustion and render life intolerable. In such cases operation may be considered, but it must be remembered that prostatic operations do not invariably relieve frequent micturition. When the frequency is due to residual urine, the removal of the obstruction will relieve it. When there is no residual urine, the result is much less certain. Riches and Muir (1933), investigating cases treated by a group of surgeons, found frequency of more than twice a night in 12 of 68 who had undergone prostatectomy. This unsatisfactory sequel may have been diminished by modern chemotherapy and by the new operations, but it has not been eliminated.

Expectant treatment is given a place by almost all urologists. Ogier Ward (1946) advised against operating for frequent micturition alone, but this important warning is not often mentioned in published reports of prostatic surgery. Of eight students' textbooks of general surgery examined by me five do not mention expectant treatment at all.

It is certainly unjustifiable to remove the prostate merely because it is enlarged and has been associated with some urinary symptoms. This fact should be made clear to the medical student. Prostatic enlargement should be regarded, like the arcus senilis of the cornea and the greying and thinning of the hair, as an anatomical feature of old age which occurs often enough to be regarded as a variety of the normal. Only when obstruction to the flow of urine is produced does it become a disease.

SUMMARY

Expectant treatment was advised in 129 cases enlarged prostate, and their progress was followed.

In 114 cases the evidence of obstruction was sl 13 patients were operated on by me after a period observation; 4 have had operations by other The period of observation varied from $9^1/_2$ to $1^1/_2$

Eighteen patients have died. Possibly the prostate w responsible in the case of 1 patient aged 91, but it is v improbable that it was in the remaining 17 cases. For t ages and duration of follow-up the death-rate was norm

Nine patients showed definite evidence of incr obstruction, and the clinical features of those cases *compared with those of the entire series.*

A progressive course occurred in only 1 patient over t age of 60.

The size of the gland was not related to the of obstruction or to a progressive course.

Trabeculation of the bladder was not a signific indication of prognosis.

Patients without any complaint of difficulty in mi tion at the first examination were rarely progressive ca

The significance of residual urine and fallacies in estimation are discussed.

Frequency of micturition is, on the whole, great in the more serious cases but is of no value in assessing t danger of progressive obstruction in the individual ca

Hæmaturia is not a significant indication of prognos

The general course of symptoms shows that patien tend to seek advice in a phase of congestion. In a co siderable number the chief symptom had much improv within a few months, and this improvement was w maintained.

The non-obstructive or only slightly obstructi prostate has a strong tendency to remain so.

The growth of the prostate seems to slow down ab the age of 60. The age of onset of symptoms depends an attack of congestion.

A non-progressive type exists and can be identifie by the absence of difficulty *in micturition* and residual urine. Such patients should be treate expectantly. When difficulty in micturition is not grea and residual urine is slight, expectant treatment shoul also be advised. A non-progressive course is likel in the older patients and in a considerable proportion o the younger ones.

Frequent micturition and hæmaturia are indication for operation only in rare cases.

I am grateful to Dr. R. A. Robb, lecturer in statistics the University of Glasgow, for his study of the mortality ra in my cases; to the almoners of the Victoria Infirmary whose enthusiasm is the reason for the very small numbe of untraced cases; and to the resident doctors, nurses, an clerks of the infirmary.

obtained. Swendseid et al. (1947) showed that the etion of free folic acid in the urine after a dose of a-γ-glutamic-acid conjugate depended on the pre- e or absence of conjugase inhibitors in the extract; hey were absent, free folic acid was excreted in unts equivalent to the dose of conjugate given.

e have not been able to test the pteroyl-hepta-γ- amic acid, but there now seem to be good grounds concluding that, if it is obtained free from conjugase bitors and a sufficient dose is given, it can be utilised he patient with pernicious anæmia in the same way ther conjugates.

he responses obtained with diopterin (pteroyl-α- utamic acid) are especially interesting, because oterin is an artificial substance with the glutamic- l molecules linked through the α carbon atoms in a nner that hitherto is not known to occur in nature. observation that patients were somewhat less ponsive to diopterin than to teropterin corresponds h the results of Jukes et al. (1947), who used urinary retion of free folic acid as a test of the hydrolysis of synthetic polyglutamic acid used; they found that, olic acid was given to a normal person, 90% of the e was excreted within 6 hours; with teroptin there s a lag, and the corresponding free folic acid appeared ween 6 and 24 hours later; with diopterin the lag s longer than 24 hours.

When it was first appreciated that patients with nicious anæmia responded to folic acid itself, and that ic acid occurred naturally in the conjugated triglutamic- d and heptaglutamic-acid forms, the hypothesis that pernicious-anæmia patient might not be able to drolyse conjugated forms was suggested by Bethell et al. 47), Heinle et al. (1946–47a and b), and Spies (1947). e early failures to obtain responses with folic-acid njugates appeared to support this hypothesis, and vidson (1948) suggested that "the fundamental defect addisonian pernicious anæmia is the patient's inability utilise pteroylheptaglutamic acid." Our results show at there is no basis for the assumption that patients th pernicious anæmia cannot hydrolyse the conjugated rms, or even utilise them directly, and the results of hers already cited have shown where the fallacy lies. is unfortunate that statements about the rôle of ic-acid conjugates in the ætiology of pernicious æmia have reached the textbooks, because the newer idence, including that about B_{12}, seems to suggest that th present knowledge neither folic acid nor its con- gates play any major part in the ætiology of the human rnicious-anæmia syndrome (Wilkinson 1948).

SUMMARY

Thirteen patients with pernicious anæmia were treated th the synthetic folic-acid conjugates pteroyl-γ- glutamic acid (teropterin) and pteroyl-α-diglutamic id (diopterin).

Eight patients were treated with teropterin alone via e intravenous, intramuscular, and oral routes. All owed normal responses with reticulocytoses and subse- ent increases of red cells and hæmoglobin. Three tients were treated with diopterin alone, intravenously d intramuscularly. The doses available were minimal, t all three showed reticulocyte responses, and reason- le increases of red cells and hæmoglobin followed. wo further patients were given diopterin and then ropterin; in one a poor response to diopterin was llowed by a good response to teropterin, whereas the her patient responded satisfactorily to both.

Continuation treatment with teropterin was given to e patients, and the blood-counts were raised to normal nearly normal levels with the doses available.

Evidence is therefore presented that patients with rnicious anæmia can hydrolyse and utilise folic-acid njugates (pteroyl-polyglutamic acids) whether of a aturally occurring γ-amino type, like teropterin, or an α-amino type, like diopterin, which does not occur in nature. There is thus no reason for supposing that in pernicious anæmia there is a failure to release free folic acid from its conjugated forms.

We wish to thank Dr. R. W. Linton and Dr. S. D. McIsaacs, of Lederle Laboratories Division, Cyanamid Products Ltd., for supplying us with these synthetic pteroyl-polyglutamic acids.

MENORRHAGIA OF EMOTIONAL ORIGIN*

J. B. Blaikley
M.B. Lond., F.R.C.S., F.R.C.O.G.
OBSTETRIC SURGEON, GUY'S HOSPITAL;
GYNÆCOLOGICAL SURGEON, CHELSEA HOSPITAL FOR WOMEN

Faced with a baffling case of menorrhagia, few consider whether the cause may be emotional. Indeed, I have found only one textbook which devotes so much as a paragraph to "psychogenic menorrhagia." This is curious, as amenorrhœa of emotional origin is well recognised. Yet this is a far commoner cause of menorrhagia than some of the others which are fully described.

The importance of recognising an underlying emotional origin of menorrhagia lies first in the possibility of cure by appropriate advice, reassurance, or even formal psychotherapy, and secondly in the avoidance of unnecessary surgery—even such radical operations as hysterectomy may have been contemplated. Psychogenic menorrhagia is in my experience easier to cure than psychogenic amenorrhœa.

CASE-RECORDS

The following cases are selected partly because of the severity of the menorrhagia and partly because their histories indicate the degree of emotional upset.

Case 1.—A rather sensitive woman in her early twenties had married a sailor. Six months after the marriage her periods began to be more profuse, the cycle shortened to a fortnight, and the period of loss gradually lengthened. When I saw her a year after the marriage she seemed healthy, and her pelvic organs were normal. I gave her a preparation of ergot with no benefit, and then, as she got worse, I did a dilatation and curettage.

After this the bleeding became more or less continuous, and the patient became seriously anæmic in two or three months. She developed a fine tremor of the hands, lost weight, and slept badly. These symptoms I attributed to anxiety; so I tackled her from the psychological aspect, as I had done before without success, and eventually persuaded her to speak out. It proved that her husband was a sexual pervert, and there had never been anything except abnormal sexual relations. The prospect of such relations continuing had become absolutely intolerable to her. As the husband refused treatment or to alter his ways I advised her to consult a society giving free legal aid and to obtain a separation order. This she obtained, and within a few days the bleeding ceased, and there was no further menorrhagia when I last saw her some months later.

---

* Based on a contribution to the Royal Society of Medicine in March, 1949.

teropterin alone, and three with diopterin alone; two had diopterin followed by teropterin. The results are shown in the table and figs. 1–3.

RESULTS

Pteroyl-tri-γ-glutamic Acid (Teropterin).—All the patients responded satisfactorily. Cases 1 and 4 show that, with an initial intramuscular dose of 100 mg. on 2 days and then, after the initial response, a dose of 40–80 mg. at intervals of about 7 days, the blood-count could be raised to levels approaching normal; case 8 shows that the same result could be obtained with a dose of 20 mg. daily by mouth. The other patients showed equally satisfactory initial responses; as with other forms of treatment, the increase in red cells and hæmoglobin varied a good deal in different patients. As supplies were limited, the teropterin treatment could not be continued very far. For this reason we could not maintain any patient on teropterin for longer than 60 days. Case 7 is interesting because the patient's initial count was exceptionally low and her general condition poor; her reticulocytes rose from 0·2 to 4·0% in 48 hours, and to 18·6% in 72 hours—a response quite as rapid as would be expected with a similar dose of folic acid. Case 3 shows that the response to a single intravenous dose of teropterin 100 mg. can also be similar to that obtainable with folic acid (Wilkinson 1948, Wilkinson et al. 1946).

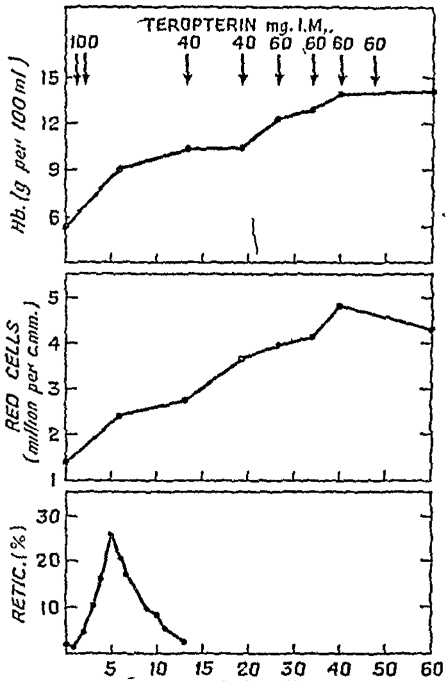

Fig. 1—Response of case 1 to intramuscular teropterin.

Pteroyl-di-α-glutamic Acid (Diopterin).—The results with diopterin suggest that we were working with minimal doses; and, since we had very little of this material, no patient was taken up to normal blood levels. A dose of 100 mg. produced a moderate reticulocyte response in case 9, but only slight delayed increases in red cells and hæmoglobin. An initial dose of 150 mg. had a similar effect in case 12, but in cases 10, 11, and 13 the increases in reticulocytes were higher and in red cells and hæmoglobin definite, though less perhaps than might have been expected with similar doses of teropterin or folic acid.

Teropterin Following Initial Treatment with Diopterin.—Case 12 shows that teropterin produced a good response in a patient who had shown only slight response to a similar dose of diopterin. In case 13 the red cells and hæmoglobin increased to nearly normal levels under treatment with teropterin after a good initial response to diopterin.

DISCUSSION

These results make it clear that patients with pernicious anæmia can utilise folic-acid conjugates, presumably by hydrolysis, and liberation of free folic acid. Provided adequate doses are given, intravenous, intramuscular, and oral administration will all produce typical reticulocyte responses followed by proper increases in red cells and hæmoglobin; the clinical state of the patient improves in exactly the same way as it does after treatment with folic acid itself (Wilkinson 1948). We believe that, if enough material had been available, these patients could have attained normal blood-counts on treatment with folic-acid conjugates alone. Whet normal counts could be maintained by conjugates, cannot yet say, but experience with folic acid it makes us cautious.

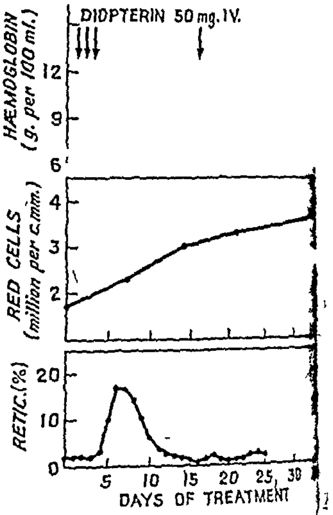

Fig. 2—Response of case 2 to intraveno diopterin.

These results are opposed to the earlier reports other workers, who suggested that patients with pe nicious anæmia *would not respond to* naturally occurr conjugates, and in fact could not utilise these compound Later investigations explain this disagreement. used the pure synthetic compounds; the earlier work had to be content with concentrates prepared fr natural sources. These concentrates had two di advantages: (1) the available dose was often too smal and (2) these concentrates are said to contain conju inhibitors that prevent hydrolysis of the folic-acid co jugates. Bethell et al. (1947), using a concentrate of th pteroyl-hepta-γ-glutamic acid, showed that irregul results were probably due to the presence of the conjugase inhibitors; when extracts with only we inhibitor activity were given to two patients wi pernicious anæmia, a reasonable hæmatological respons

ement a month before since she had decided that the age would not be a success; none the less she was upset, because she had been engaged for two years and than once had slept with the man. She had lost her spect.

ittle reassurance and encouragement went a long way. two months later she was much better, the periods had less painful, and there was little menorrhagia. She had e examination but did not know the result. For the last ionths the periods have been normal (she passed the ination).

se 8.—A married woman, aged 31, complained of rrhagia and polymenorrhœa for 18 months. For a year leeding had been more or less unceasing, the loss being y slight. Latterly there had been some slight improve-, inasmuch as she had twice had an interval of a week from bleeding. For 10 months she had been sleeping , staying awake till 4 A.M., and she had not been eating These symptoms dated from an attack of measles. Her r had given her 'Antuitrin S' for several months ut benefit.

amination showed nothing abnormal in the pelvis; so uired about her past life. She had been engaged before ar, and after six years the engagement had been broken utual agreement. She had become engaged again during ar, and her fiancé had been blown up by a land-mine in andy, both legs being badly injured and later amputated. as in hospital for a year or so in this country, and when could get leave from the A.T.S. she would make long eys to see him and try to cheer him up. He wanted to and she had a long and difficult time persuading him to At the end of this time he broke the engagement. She much upset but decided to keep her troubles to herself be matter-of-fact about it, since her mother was in ill th and her father was abroad. She had slept badly at time. Six months later the menorrhagia had begun n. According to the patient her fiancé had been mentally rmal ever since his injuries and remained so; she corresponded with his mother.

ough I considered this a case of emotional menorrhagia ought it wise to do a diagnostic curettage, but the patient ed. Her doctor writes to say that the patient's mother is nt on making her daughter a chronic invalid, and that it e who opposed admission to hospital.

DISCUSSION

n these cases the proof of an emotional origin for the iorrhagia lies largely in the recovery that takes place n the emotional state returns to one of tranquillity. hat strikes me about all these cases is the severity the menorrhagia, in particular the long spells of ding and the way in which it continued until the chological difficulties were dealt with. I had realised t the anxiety of coming into hospital for operation n brings on a period, and that many emotional situa-s produce a single heavy period, but I had not reciated that long-continued menorrhagia of this ree could be entirely psychogenic. Incidentally, it very obvious during the war that fatigue was a ly frequent cause of menorrhagia—e.g., members of W.A.A.F. engaged on night work, plotting enemy craft, complained of this, and all that was required in se cases was a change to day work and a less exacting . Many of these patients presenting themselves with norrhagia as the prominent symptom are referred specialist physicians and good general practitioners o have never suspected its psychological origin. Many these patients are normal women subjected to excessive otional strain; there is usually a delay of 6–12 onths from the onset of the strain before the menor-agia starts. Often, but not always, other symptoms e present suggesting a psychogenic origin, such as eeplessness and being easily tired.

I can confirm what other workers have stated—that permenorrhœa (increased length of the period rather an increased flow) is common, as is a shortened cycle olymenorrhœa)—but true menorrhagia is also common. believe that many intermenstrual bleedings are of notional origin. I have come to think that many patients diagnosed by gynæcologists as having mild hyperthyroidism causing menorrhagia are suffering from anxiety states. I have waited unsuccessfully many years to see a case of menorrhage due to this cause, and I agree with those thyroid surgeons who believe hyperthyroidism is never a cause of menorrhagia.

Miller (1931) says: "My experience with many forms of menorrhagia has led me to believe that the majority of them, if not all, are purely psychical in origin and because of this, are curable non-medicinally and non-surgically." I would not go so far as this, but I have found drugs and endocrines singularly ineffectual, though the latter may control an individual period to some extent. Curettage is of diagnostic value, but other surgical measures are to be avoided. I believe that most menorrhagias when the endometrium is normal are to be explained as being psychogenic.

Allen (1935) published a study of more than a hundred patients in a mental hospital with menstrual disorders; in his summary he says:

> "These menstrual variations seemed to be somewhat characteristic of the different types of personality disorders, but only because of the different emotional reactions which they presented. . . . The emotional factor was the only one that appeared to have a definite correlation, both *quantitatively* and *qualitatively* with variations in the menstrual function. . . . A depressive mood, physical depletion and motor underactivity are conducive to amenorrhœa. . . . An expansive, elated or ecstatic mood, with good physical condition and motor overactivity, predisposes to a profuse and prolonged period. Agitation and worry are more apt to be associated with a profuse than a decreased flow."

From my own experience I would say this is true.

The normal reaction of a person to difficulties he can recognise and understand is to fight back, and there is increased nervous activity, which is widespread. A common reaction to obscure and ill-appreciated difficulties is one of increasing apathy, with decreased nervous activity. Several workers have noticed comparable changes of activity in different organs in these differing circumstances. Wolf and Wolff (1947) describe the case of a man, aged 57, who had a large gastrostomy opening (for stricture of the œsophagus) with prolapse of the gastric mucosa.

> He was perhaps more emotional than the average man but not abnormally so. Changes were observed in the colour of the mucosa according to his emotions and were accompanied by corresponding but slighter changes in the colour of his face. The emotionally charged situations were not produced experimentally but occurred spontaneously. Fear, with a feeling of helplessness, caused short-lived blanching; sadness, discouragement, self-reproach, and anything which caused depression caused protracted blanching. On the other hand, anxiety or alarm which provoked action, and particularly resentment and hostility, caused well-marked and long-continued flushing. The most striking observations were made over a period of five weeks during which the patient was suffering from prolonged anxiety, frustration, and resentment, with much repressed conflict. During all these five weeks, whether he was waking or sleeping, a persistent hyperæmia was noted. The observers noted that when the gastric mucosa was hyperæmic, it more readily registered pain and discomfort, and it took very little to make it bleed. Flushing or blanching of the gastric mucosa seemed to be part of a general reaction.

Wolff (1947) shows that not only does the mucosa of the stomach alter in vascularity with the emotional state, but also the mucosa of the nose, bladder, large bowel, and vagina.

Almy and Tulin (1947) describe experiments made on seven healthy male students, who were subjected to severe discomfort until they felt nauseated and were sweating; their colon mucosa was observed through a prostoscope inserted before each experiment began. In every case the vascularity and secretion from the mucosa and the motility of the bowel were increased.

Mittelmann (1946) found that fear, dejection, and disgust were associated with pallor of the nasal mucosa and decreased

It has been suggested that continual bleeding can occur as a defence mechanism to make it impossible for coitus to take place, but in this case the cause I believe was anxiety and disgust, giving rise to unrelieved emotional conflict, since the patient had felt unable to leave her husband.

Case 2.—I first saw this patient on March 13, 1945, when she was 29 years old and had a young child. She complained of menorrhagia, which had begun about six months after her marriage three years previously and had recurred whenever she had difficulty with her husband, which was fairly often. On Jan. 6 he had produced a revolver and threatened to shoot her. He had often been violent, and as he was a powerfully built policeman she had become seriously anxious for herself and the child. She had bled almost continuously since Jan. 6 and was obviously anæmic. She had become "nervy" and complained of an odd sensation in the throat. On questioning, it came out that her husband had always been a sexual pervert, and unpleasant happenings occurred increasingly often. She had never told her doctor this, because she had remained very fond of her husband.

I explained to her that her severe emotional strain was the whole cause of her menorrhagia, and in the interests of her health she must separate from her husband immediately, and preferably divorce him as soon as possible. The husband refused to admit he was abnormal and to consult a psychiatrist. The patient took my advice and during the next $2^1/_2$ years was much improved; she then got her divorce and her periods immediately became normal.

I saw her again six months after her divorce, when she had married again. She was complaining of nine weeks' amenorrhœa, apart from a very scanty loss while taking stilbœstrol, and feared she might be pregnant. She had been given stilbœstrol for three weeks, finishing a week before I saw her. I reassured her, and within two days she had a normal period. This was possibly due to the withdrawal of the stilbœstrol. Her periods have since remained normal, and she is very well and happy.

It is of interest that the same woman had menorrhagia at one time and oligomenorrhœa at another, both due to anxiety.

Case 3.—A married woman, aged 30, complained of almost continuous bleeding for three months. Her husband was making excessive sensual demands on her, and these were occasionally abnormal. Sexual relations had become repulsive to her for the past year, and she had remonstrated with her husband without avail. She was very fond of him, and there was mental conflict about what to do.

I suggested diagnostic dilatation and curettage, but this was refused. As I thought the menorrhagia was emotional in origin I spoke to her doctor, and he took the matter up with the husband, who mended his ways and behaved normally for some months. During this time the patient's periods returned to 7 days every 28.

The husband has recently reverted to his former habits and now includes physical violence in his behaviour towards his wife. The result has been that the periods have become heavier and more frequent, lasting 10 days every 20.

Case 4.—A woman, aged 23, came to me with her first pregnancy at term. There was disproportion, and I advised a trial labour. Shortly afterwards I saw her again, when she had been in labour 24 hours with poor pains; she was in a state of considerable apprehension, which neither her doctor nor I could dispel. I delivered her by cæsarean section. For the next eleven months she bled continuously, apart from three breaks, one of 14 days while a kindly nurse, an old friend, stayed with her, and two of 4 days, one of which followed a dilatation and curettage eight months after the cæsarean section. The dilatation and curettage revealed nothing abnormal. The patient was living in her mother-in-law's house; she liked her mother-in-law, but found her sister-in-law and her child very trying. The sister-in-law was playing fast and loose with various young men, and the child was obstreperous. During all this time the patient was tense and easily agitated. Shortly after she had moved to a house of her own the bleeding stopped and the periods became infrequent and irregular, every 2–4 months, but lasting 12–14 days with heavy loss.

I saw her $2^1/_2$ years later, when she was upset at not having become pregnant again; she felt she was always a failure, in that first she had had to have a cæsarean section and now she could not become pregnant. She was quite about it, was sleeping badly, had nightmares, and agitated. The periods for 10 weeks had been irregular, or so loss, with 1–14 days' interval. Examination normal uterus.

It came out that she had been raped, when only 12 old, on more than one occasion by the same man, and I sure this was responsible for her general state of emotional tension, which she tried to counter with her will; she had lived for months in extreme apprehension— thing she expected the family doctor to knock at the door and present her with a baby any day. She had months' amenorrhœa at this time; this may or may not been a sequel. I talked to her for some time on two and reassured her about the prospects of having child, and told her that with proper management a delivery was probable.

I have learnt since from her doctor that she is and that menstruation is very irregular still. She fears to sleep because she dreams of being raped in front of husband and child. This is the first time she has brought self to tell of her dreams, which we knew were unpleasant.

Case 5.—A rather neurotic woman, aged 31, menorrhagia for three months, the periods lasting 5 or 6 d every fortnight. Her husband, also a neurotic, had been in the Forces, and after his return she had noted he "cool." She had found he was conducting an affair another woman; this had lasted for six months before he h given it up. He had regretted having hurt his wife's feeli and had tried to make it up, but he had begun to have nerv symptoms, and these had caused his wife much anxie because they were genuinely fond of each other. In additi to menorrhagia, the wife complained of headaches, dyspn and palpitation. Her hæmoglobin was only 66% (Halda I referred her to Dr. D. F. O'Neill, who undertook psychia treatment of both husband and wife, and within three mont the periods became normal. Menstruation has remain normal up to now.

Case 6.—A woman, aged 24, complained of 18 mont menorrhagia. The periods lasted 7–10 days, and there w heavy loss. There was also "spotting" for 3 or 4 days befo a period and half-way between. Also if she got excited upset she would have slight spotting or even an embarrassi loss. This would happen usually when she stood up af some emotional experience—e.g., seeing an exciting film Sh slept badly and felt very tired. Her family history showe some mental instability, but her childhood had been happy though the family was always on the move. On leaving scho she had tried to do nursing, but the work was too heavy, and she was advised to give it up. At that time she had ha menorrhagia and excessive fatigue. In 1946 she had marrie and gone to the U.S.A., where she lived with her in-la who were noisy and argumentative. One of the family was in trouble with the police, and she had lived in a state of apprehension; every time there was a knock at the door she thoug it was the police come for her brother-in-law. She had fall out with her mother-in-law, who accused her of stealing th things her brother-in-law had taken. During this time sh had developed severe menorrhagia. She was definitely woman of hysterical personality, and she had always foun her periods more profuse than normal and affected b emotional states and changes in climate.

When I saw her she was still unhappy and frustrated; sh had no work and was temporarily separated from her husband I found no organic disease and referred her to Dr. O'Neill who gave her simple psychotherapy and advised her to com to him occasionally for supervision. During the short tim she was under observation she was much improved. Sh then returned to the U.S.A. where she reports that she i quite well.

Case 7.—A young single woman complained of menstrua irregularity and menorrhagia. She had had a heavy perio lasting 6 or 7 days in March, 1948, with pain; this had bee followed by a normal period in April; a week later she ha lost for one day; and in May she had had a heavy loss for week, accompanied by pain. She had been sleeping badly fo a month.

Physical examination showed nothing abnormal. Inquirie about worries revealed that she had failed an examinatio twice and was anxious about the third attempt, then nearly due; a further failure she thought would upset her mother, an ill woman, rather badly. Further, she had broken off her e Tween 80 albumin medium. When growth had n. two to three drops were inoculated into a second of the medium. After 8–10 days' incubation at inocula of 0·02 ml. were distributed with a pipette rated to drop 50 drops per ml. to a series of tubes aining streptomycin in concentrations of from to 0·06 units per ml. by twofold steps. A standard n of *Myco. tuberculosis*, H37RV, was maintained on kauer and Beck's medium (Steenken and Gardner), and on each occasion a sensitivity test was done t by the same technique carried out in parallel. lts of the sensitivity tests were read at 10 days and ribed relative to the standard strain. Thus, if the st tube in which growth was completely inhibited ained 0·5 unit per ml. for the standard strain and it per ml. for the strain under test, it was described two times less sensitive than H37RV." For the pose of analysis the results were expressed on a rithmic numerical scale as follows, a difference of on this scale corresponding to one tube up or down he sensitivity test:

	Numerical scale
4 times more sensitive than H37RV	1
2 " " " " "	2
Sensitivity equal to that of H37RV	3
2 times less sensitive than H37RV	4

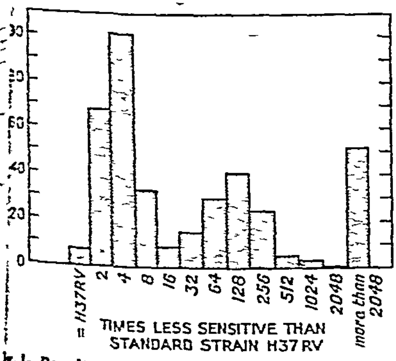
1024 times less sensitive than H37RV ..	13
2048 " " " " ..	14
More than 2048 times less sensitive than H37RV	15

Subcultures from the original egg slope into Tween 80 lumin medium were usually made as soon as growth became apparent. In view of the possibility that sensitive and resistant organisms might grow at different rates, 67 of the original slopes were sampled immediately growth became apparent, which was at an average 23 days after incubation. They were then eincubated and retested after eight weeks had elapsed ince inoculation.



g. 1—Results of sensitivity tests on 398 strains of *Myco. tuberculosis* resistant to streptomycin.

To obtain an estimate of the errors involved in measurng the degree of sensitivity of resistant strains 55 sputa rom patients who had expectorated resistant strains were ultured in duplicate and sensitivity tests were done n both the strains obtained.

RESULTS

Pre-treatment Strains

Results obtained on strains derived from patients before the start of streptomycin therapy are given in the accompanying table. 14 sputa were each divided into two portions and cultured separately. As can be seen from the analysis of variance, the variation between these duplicates is similar to that between strains obtained at different times from the same patient. Further, the amount of variation between the strains derived from different patients is the same as the amount between the different strains derived from the same patients. Thus it can be concluded that, within the limits of the accuracy of the technique, there is no real difference in the sensitivity of strains derived from different patients.

RESULTS OF SENSITIVITY TESTS DONE ON 205 STRAINS OF *Myco. tuberculosis* DERIVED FROM PATIENTS BEFORE TREATMENT WITH STREPTOMYCIN

	No. of strains
4 times more sensitive than H37RV ..	2

ANALYSIS OF VARIANCE

—	Sum of squares	Degrees of freedom	Mean square	F	P
(1) Between patients ..	43·4592	123	0·3533	1·162	0·2
(2) Between strains ..	29·2482	67	0·4365	1·528	0·2–0·1
(3) Between duplicate cultures of the same strain	4·0000	14	0·2857		
(4) Total within patients (2 + 3)	33·2482	81	0·4105		

The mean square derived from the duplicate cultures of the same strain has been used to test the significance of the between-strains mean square. The total within-patients mean square has been used to test the significance of the between-patients mean square.

Resistant Strains

The results of sensitivity tests on 398 strains are given in fig. 1. There appear to be three distinct groups of strains showing a characteristic degree of resistance. In one of these groups they are about four times less sensitive than H37RV. In the second group they are about 128 times less sensitive, and in the third group the strains can grow in at least 1000 units of streptomycin per ml., the highest concentration used.

Among individual patients there is usually a more or less abrupt rise from a strain as sensitive as the pretreatment strain to one or other of these levels of resistance. In most cases once this level has been attained it is maintained throughout treatment. Thus in a group of 12 patients developing a degree of sensitivity four times less than H37RV (a typical example is fig. 2A) only one showed any tendency to develop a higher degree of resistance. In this case (fig. 2B) the initial change in sensitivity occurred at 23 days and the second change, which was abrupt, at 79 days after the beginning of treatment. In the remaining 11 patients the change in sensitivity occurred on the average at 65 days (range

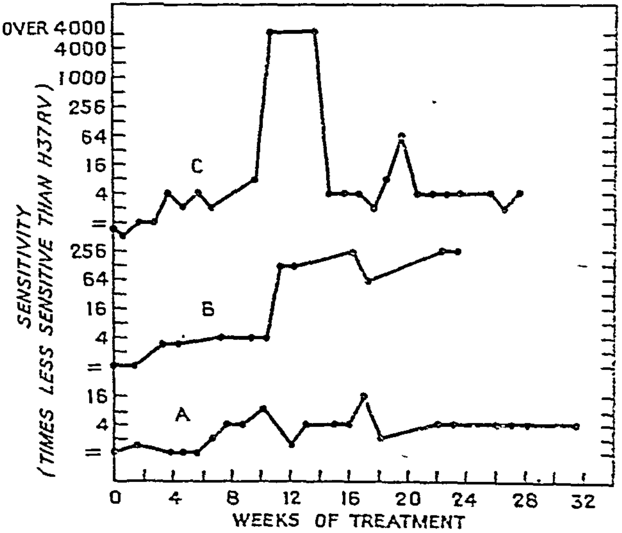

Fig. 2—Results of sensitivity tests to streptomycin done on strains isolated from individual patients: A, typical series of strains developing a degree of sensitivity four times less than H37RV: B, series of strains demonstrating development of resistance in two stages; C, series of strains showing wide fluctuations in the resistance.

secretion, whereas anxiety and resentment were associated with hyperæmia and swelling of the nasal mucosa and increased secretion.

It therefore seems likely that all mucosæ react similarly, and that menorrhagia of emotional origin is brought about by vasodilatation and hyperæmia of the endometrium.

It has been shown in other organs, such as the stomach, that it takes very little to make a hyperæmic mucosa bleed. I suspect that the uterine muscle is slightly irritable and that its contractions may be the final factor in causing the bleeding (see below). The hyperæmia alone may well be the cause in the case of the endometrium.

Admittedly, the menstrual cycle is often shortened, but this is probably due to over-reactivity of the cerebral cortex and consequent disturbance of the hypothalamus, which controls the cycle through the pituitary. What disturbance there is of endocrine function is secondary to this, and curettings do not suggest that an excess of œstrogenic hormone is a factor in the menorrhagia. This theory is supported by the following case of postmenopausal bleeding in which œstrogens can have played little part.

Case 9.—In February, 1946, the patient was 58 and her menopause had taken place exactly two years previously. In November, 1945, bleeding had occurred, profuse at first, and lasting a week; another gynæcologist had done a curettage but found nothing.

When I saw her, there had been further slight bleeding, but all I could find was a small erosion which was hyperæmic and bled at the slightest touch. I applied silver nitrate. Three months later I saw her again for further short spells of bleeding. She also complained of pains in the groins and loss of weight. I found slight bleeding from the cervical canal, and the body of the uterus was slightly tender. I therefore did a diagnostic curettage. I found that both the endometrium and the small erosion bled readily; the mere passage of a sound started free bleeding from the endometrium, but I could remove nothing. The erosion I cauterised.

I had not expected to find anything, for I had discovered that the bleeding occurred in every case on the birthday, or day of death, of one of her sons: all three sons had been killed in the R.A.F., and shortly after that her husband had died. The patient had never recovered from her distress. Latterly she had been busy helping her daughter with her small family and had got rather tired. She is easily agitated and cannot readily express her emotions; she undoubtedly has a labile vasomotor system and flushes very readily. I explained the situation to her and gave some simple advice, and she has had no more trouble.

In this patient there was slight bleeding from an erosion which was hyperæmic. It is reasonable to infer that the endometrium was similarly hyperæmic, and that this was why it bled so readily.

When doing a hysterectomy on women whom I have thought to be a little over-emotional I have several times noted that the uterus flushes and blanches, and flushes again. The endometrium has appeared normal, and I believe I have done hysterectomies where the cause, or at least an important aggravating factor, has been emotional.

Fremont-Smith and Meigs (1948) describe a case of menorrhagia due to emotional factors. They had given intensive endocrine therapy and curetted the woman; both treatments were singularly ineffective. Bleeding finally ceased after three hours' discussion with a psychiatrist, during which care and anxiety were partially relieved. The woman had bled almost continuously for nine months, and two endometrial biopsies during this time showed normal proliferative œstrogen changes in the endometrium. She had been followed up for nine years, and her periods have remained normal during all this time.

It occurs to me that the first recorded case of menorrhagia of emotional origin is to be found in the Gospel according to St. Luke, chapter 8, where it reads: "A woman having an issue of blood twelve years, which had spent all her living upon physicians, neither healed of any, came behind him, and touched the of his garment: and immediately her issue of stanched." No doubt, from her faith, she got mind for the first time for many years. It is how quickly the bleeding can stop, and this think points to a psychogenic control in these cas

SUMMARY

Eight cases of menorrhagia in which the bleedi associated with emotional difficulties, and a case o menopausal bleeding of psychogenic origin are Such menorrhagia is not uncommon, particul young women. It can be cured by simple psy

I wish to thank Prof. W. R. Spurrell for his criticism, and Dr. O'Neill for his interest and help treating two of the cases.

TESTS FOR STREPTOMYCIN SENSITIVITY OF TUBERCLE BAC IN TWEEN 80 ALBUMIN LIQUID MEDI

D. A. Mitchison*

M.B. Camb.

LECTURER IN BACTERIOLOGY, POSTGRADUATE MEDICAL
OF LONDON; FORMERLY ASSISTANT TO THE PATHOLO
HOSPITAL FOR CONSUMPTION AND DISEASES OF
CHEST, BROMPTON

For two years, strains of *Mycobacterium tube* have been tested for their sensitivity to strept in the 'Tween 80' albumin liquid medium de by Dubos and Davis (1946). Results from two of strains are described here, one obtained from p before receiving streptomycin, and the other o after increased resistance to streptomycin had dev

STRAINS OF *Myco. tuberculosis*

All the strains except 2 were obtained from p receiving streptomycin under the auspices of the S mycin in Tuberculosis Trials Committee of the Research Council. 205 strains were obtained fro patients before treatment started. 89 of these p had pulmonary tuberculosis, and 35 miliary or me tuberculosis. 398 strains showing increased res to streptomycin were obtained from 61 patients. 4 of these were obtained from the meninges; t were cultured from sputum, gastric lavages, or la swabs. Cultures were taken at short intervals treatment (usually weekly) from 27 patients pulmonary tuberculosis. Whenever a strain fro of these patients had become more than "two tim sensitive" (see below) to streptomycin than the st strain H37RV it was deemed resistant, and all subs strains obtained from that patient were included the resistant cultures.

METHOD

The method used for determining the sensiti streptomycin has been described by the Patho Subcommittee of the *Streptomycin in Tube* Trials Committee of the Medical Research C (Medical Research Council, 1948). Strains of *tuberculosis* were isolated on egg media, and represen samples of growth were transferred to 3 ml. qua

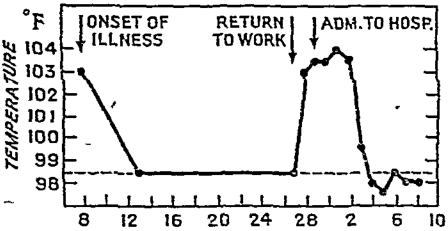
Case-report

nan. aged 42, was admitted to Ruchill Hospital on 29, 1948, for investigation of pyrexia of unknown . For twenty years he had been employed as a sheep- in the city abattoir, where he had often been bitten ks and had commonly brushed them off his arms and ıck of his neck.

had been well until three weeks previously (Sept. 8) he was taken suddenly ill with what he described as ıd attack of flu." At that time, he complained of sore t and joint pains. His family doctor found that his ɜrature was 103°F (see figure) and that he had mild hitis and faucial inflammation. This febrile illness ıued for five days. Aspirin and an expectorant cough- ıre were prescribed and the patient seemed to recover letely.

felt well enough to go to work on Sept. 27, but after a ıours went home, complaining of severe headache and asing weakness. On Sept. 28 he again sought his doctor's e, because of intense headache, vomiting, constipation, profuse perspiration. His temperature was 103°F and pulse-rate ermin., but mination ıed no other ırmality. On t. 29 he ıloped slight ıal rigidity, ıt internal bismus, and apular rash he abdomen, l he was ıitted to hos- l for further stigation.



Biphasic pyrexia in a patient with louping-ill.

n hospital the patient complained of bouts of severe fronto- ipital headache and of transient attacks of diplopia. was mentally alert and cooperative. On admission his ıperature was 102°F. He looked ill and had mild photo- bia; he had a malar flush and perspired freely; a few all pink papules were observed on the skin of the abdomen the para-umbilical region. The tongue was heavily furred d there were sordes on the lips; the throat was not lamed. The abdomen was not distended and the liver and een were not enlarged. The respiration-rate was 34 min.; neither cyanosis nor respiratory embarrassment s present, but numerous râles were heard throughout the g fields. The pulse (rate 110 per min.) was of good volume d regular; the blood-pressure was 110/65 mm. Hg. The art was not enlarged and the heart sounds were pure and good quality. Right internal strabismus and slow lateral stagmus were noted, but no other abnormality on full amination of the central nervous system. Ataxia was sent. Ophthalmoscopic and auroscopic examinations also ealed no abnormality.

INVESTIGATIONS

Urine analysis proved negative. Lumbar puncture yielded clear fluid under normal pressure with 120 lymphocytes r c.mm., increased protein, and a normal chloride content e table I). The white blood-cell count was 16,000 per mm. (polymorphs 85%, lymphocytes 12%, monocytes 3%). assermann and colloidal-gold tests were negative. The Widal and the Paul-Bunnell tests, and the Schuffner test for *Leptospira icterohæmorrhagiæ* and *L. canicola*, were all negative. Repeated radiological examinations of the chest showed no evidence of pulmonary disease. Bacteriological examination of fæces and urine for the dysenteric and enteric groups of organisms also proved negative.

TABLE I—CEREBROSPINAL FLUID IN PATIENT WITH LOUPING-ILL MENINGO-ENCEPHALITIS

Date	Character	Pellicle	Lymphocytes per c.mm.	Chlorides mg. per 100 ml.	Sugar mg. per 100 ml.	Protein
Sept. 30	Clear	Nil	120	715	50	Increased
Oct. 2	Opalescent	Nil	320	740	70	Increased
Oct. 11	Clear	Nil	52	720	60	50 mg. per 100 ml.
Oct. 19	Clear	Nil	18	780	60	60 mg. per 100 ml.

TREATMENT AND PROGRESS

Pyrexia (100–104°F) persisted for five days, after which the temperature fell by crisis. Double vision recurred intermittently for three days and then passed off. The nystagmus, too, was transient and disappeared two days after admission. The fronto-occipital headache came in bouts of great severity for four days after admission, but then these stopped as quickly as they had begun. The right internal strabismus recovered as the headaches improved; and all abnormal signs in the central nervous system had disappeared on the fourth day after admission.

Initially, symptomatic treatment was employed, but on Oct. 2, in view of persistent pyrexia and chest signs, a course of sulphadiazine (2 g. four-hourly) and intramuscular penicillin (50,000 units four-hourly) was instituted.

The patient made an uneventful recovery. The chest signs were the most resistant to treatment. Sulphadiazine was discontinued on Oct. 7, but penicillin was administered until Oct. 19, when the chest was pronounced clear, clinically and radiologically. The patient was discharged from hospital on Nov. 29, and resumed his work in the abattoir. On the day of his discharge a sample of blood was dispatched to be examined for the presence of neutralising antibodies against the virus of louping-ill.

SERUM-NEUTRALISATION TESTS

Various dilutions of the virus of louping-ill were mixed with an equal volume of the patient's serum. As controls, similar dilutions of the virus were mixed with normal horse-serum and with another human serum. The results are shown in table II. While the horse-serum and the control human serum showed no activity whatsoever against the virus, the patient's serum was highly active. Given by the intracerebral route it neutralised the virus completely in a dilution of 10^{-6} and retarded infection slightly with other dilutions. When the virus-serum mixture was inoculated intramuscularly there was complete neutralisation of the virus. There is therefore strong presumptive evidence that the recent illness suffered by the patient was louping-ill.

ABLE II—NEUTRALISING ACTIVITY AGAINST LOUPING-ILL VIRUS OF NORMAL HORSE-SERUM AND SERA FROM HUMAN CONTROL AND PATIENT

Dilution of virus	Normal horse-serum		Human control		Patient	
	Intracerebral	Intramuscular	Intracerebral	Intramuscular	Intracerebral	Intramuscular
10^{-3} ..	..	6, 9, 9, 9, 9, 10	..	S, 9, 9, 10, 10, 11	..	S, S, S, S, S, S
10^{-4} ..	5, 5, 5, 5, 5, 5	8, 9, 10, 11, 13, 13	5, 5, 5, 5, 5, 5	8, 9, 10, 10, 11, 12	7, 7, 7, 7, 7, 10	S, S, S, S, S, S
10^{-5} ..	5, 5, 5, 7, 7, 7	9, 9, 11, 12, S, S	5, 5, 5, 5, 5, 5	9, 10, 10, 10, 13, S	7, 7, 7, 8, 8, 10	S, S, S, S, S, S
10^{-6} ..	7, 7, 7, 7, 7, 7	..	7, 7, 7, 7, 7, 7	..	S, S, S, S, S, S	..

Equal parts of serum and of virus in the dilutions stated were mixed and allowed to stand 1 hr. at room-temperature. The mixture was then injected intracerebrally (0·03 ml.) or intramuscularly (0·1 ml.) into mice. The numerals show the survival-period, in days, of individual mice.
S = animal survived.

44–75 days). Treatment was maintained for six months (*in 1 patient for five months*).

In exceptional cases there may be wide fluctuation in the degree of sensitivity of strains obtained after resistance has developed. An example of this is fig. 2c. It will be noted that even here the degree of resistance of any individual strain fell into one or other of the three groups.

The results obtained from duplicate cultures of resistant strains and the results obtained from cultures sampled immediately growth was observed and after eight weeks' incubation were subjected to analysis according to methods given by Kendall (1943). The amount of variation in the sensitivity to streptomycin between duplicate strains of a resistant organism (mean square 0·7105) is larger than that found for the pre-treatment strains (mean square 0·4044). This is to be expected, since the population of bacilli is probably less homogeneous. The inherent error in a sensitivity test on a resistant strain is about one tube up or down in 1 out of every 4 tests. There is no real difference in the degrees of sensitivity obtained from cultures sampled when growth became apparent and after eight weeks' incubation. The mean of sensitivity tests done on resistant cultures sampled immediately was 5·4141, and sampled after eight weeks' incubation 5·2656. The probability of this difference occurring by chance is between 1 in 3 and 1 in 2. There is thus no evidence to suggest that the result of the sensitivity test was influenced by the length of time during which the original primary culture was incubated.

DISCUSSION

The remarkable degree of uniformity in streptomycin sensitivity found among strains of *Myco. tuberculosis* before treatment was started may prove to be of epidemiological value. Any such strain isolated in the future and found to be resistant would suggest that the infection had been transmitted from a patient with tuberculosis who had undergone streptomycin treatment. For this reason it is important that the sensitivity of pre-treatment strains should continue to be tested.

Pyle (1947) has suggested that there are a few streptomycin-resistant bacilli within any predominantly sensitive strain, and that the development of resistance is due to these strains taking the place of the normal population. Yegian and Vanderlinde (1948) estimate resistant variants to be present in a proportion of from 0·36 to 6·0 per 100 thousand million sensitive organisms before treatment. If we accept this view, the occurrence of three groups of resistant strains with characteristic degrees of resistance could be explained by the hypothesis that there are three different types of resistant variants within any pre-treatment population. The proportions in which these might occur and the factors tending to favour the selection of one or other type have not, however, been determined. Further work to provide evidence for this view is in progress.

The occurrence of one group which is, on the average, only about four times less sensitive than the standard strain suggests that, in looking for the development of resistance, at least 2 strains from any patient should be tested. The variation inherent in the technique of testing is such that strains on the average four times less sensitive will often appear only two times less sensitive, whereas a strain on the average as sensitive as the standard strain will often also appear two times less sensitive and on rare occasions even four times less sensitive. The question naturally arises whether these strains showing only a slight degree of resistance are inhibited in their growth by streptomycin concentrations found within the lesion of patients under treatment with streptomycin. Evidence will be presented later that the rate of excretion of tubercle bacilli from patients with pulmonary lesions falls while the strains ar *sensitive and then rises again during the* period strains show this slight degree of resistance.

SUMMARY

205 strains of *Myco. tuberculosis* obtained
treatment with streptomycin were found equally
to streptomycin when tested, in Tween 80
liquid medium.

398 strains showing resistance to streptomycin
into three groups, each showing a characteristic
sensitivity.

The increased resistance of strains belonging to
of the groups, which are on the average only fo
less sensitive than the standard sensitive strain,
be observed unless two or more strains are tested
any one patient.

The length of time during which the primary cu
is incubated does not affect the result of the sensit
test.

The streptomycin used was the hydrochloride (M
Rahway, N. J., U.S.A., batch no. 294) and the cal
chloride complex (Merck, batch no. 1086). A unit
equivalent of one microgramme of the pure base. My t
are due for technical help from Miss R. Weitz, Mrs
Mitchison, and Miss M. Girvan.

LOUPING-ILL MENINGO-ENCEPHALIT

A FURTHER CASE AND A SEROLOGICAL SURVEY

JAMES H. LAWSON
M.D. Glasg., D.P.H.
ASSISTANT PHYSICIAN-SUPERINTENDENT

W. G. MANDERSO
M.B. Glasg., F.R.F.P.
RESIDENT PHYSICIAN

RUCHILL HOSPITAL, GLASGOW

E. WESTON HURST
M.D., D.Sc. Birm., F.R.C.P.
HEAD OF SUBDIVISION OF MICRO-ORGANISMAL RESE
IMPERIAL CHEMICAL (PHARMACEUTICALS) LTD.

FOR many years louping-ill has been recognis
responsible for a considerable mortality in sheep o
farms in the Highlands and Lowlands of Scotland
in the northern counties of England. The infe
which takes the form of a meningo-encephalomy
is due to a filter-passing virus, and the sheep-tick I
ricinus is the natural vector.

In man louping-ill is much less common. Da
et al. (1948), adding 2 cases to the 6 previously reco
pointed out that these 2 were the first in which
disease was recognised as occurring naturally
outside the laboratory. The 2 patients came fr
known louping-ill area in the North of England;
first was a veterinary officer concerned with s
dipping, and the second a farmer. More recently B
et al. (1949) have recorded a case in a shepherd w
flock was known to be heavily infected with loupi
and Edward (1948) has reported 12 more infectio
laboratory workers.

This article records a 4th example of loupi
meningo-encephalitis arising outside the laboratory;
patient was a sheep-killer employed in a Gla
abattoir. In addition we report the results of a serolo
survey undertaken to decide whether there was unr
nised infection among the patient's fellow workers.

s were unsuccessful. Hurst (1936) showed that rimental introduction of the virus of equine encepha- into the body is followed by a phase of systemic iplication and later by the disappearance of the s from the blood and its appearance in the brain cerebrospinal fluid; he believed the course of louping- n animals and man to be similar. Observations in ing with this supposition were made by Edward 8), who recovered the virus in 5 of his cases diagnosed he acute stage, by the intraperitoneal injection of ted samples of blood into mice; and by Brewis his colleagues (1949) who succeeded in isolating the ve agent in cerebrospinal fluid obtained from their ent during the stage of nervous involvement. side the laboratory, cases in the premeningeal stage nfection will seldom be recognised; so recovery of virus from the blood at the onset of the illness is kely. Diagnosis must depend primarily on the recog- on of the nervous symptoms. While these are present, Brewis and his colleagues point out, inoculation of the brospinal fluid intracerebrally and intramuscularly mice is the appropriate diagnostic procedure.

Unfortunately, when arrangements were finally com- ted for experimental investigations in our patient, was too late to attempt isolation of the virus from cerebrospinal fluid. Nevertheless, the circumstances ler which infection took place, and the results of the um-neutralisation tests suggest that the illness was ping-ill. The nervous manifestations which ushered the second febrile phase of the illness were mild d rather indeterminate. Their non-specific character phasises the necessity of laboratory diagnosis in arating this disease from other forms of virus encepha- is giving rise to similar symptoms. Headache, vomiting, d nystagmus were prominent and were associated th strabismus and diplopia. Clinical signs of meningeal itation were absent by the time the patient was mitted to hospital. The characteristic cerebellar axia noted particularly by Brewis and his colleagues as absent. The cytological and biochemical findings the cerebrospinal fluid were similar to those found in her forms of virus meningo-encephalitis.

A retrospective diagnosis of louping-ill in 3 out of of our patient's fellow workers might suggest that e occupational risk of infection is not as great in the ld as in the laboratory, where the workers handle e virus. The number of cases is, however, too small r comparison. Of the 18 reported examples of the sease contracted in the laboratory, some were diagnosed the acute stage while others were brought to light the result of serological surveys. Only 3 cases have een recognised in the field, where, as far as we are ware, no similar surveys have been performed. Macleod 1939) has pointed out that cattle grazing in infected astures readily contract the disease, and pigs and orses are known to be susceptible. It has been thought hat some cases of severe meningitis and encephalitis n man were due to louping-ill; and probably more omprehensive surveys in the louping-ill areas of Scotland ould reveal instances of the infection which, owing to he absence of nervous involvement, pass unrecognised.

With regard to the mode of infection in the laboratory, Edward mentions the possibility of contamination of the air by infected droplets, especially where techniques used in the study of viruses include the mechanical fragmentation of infected animal tissues. Such a method of transmission cannot, however, account for cases among those who simply killed and skinned infected sheep under cover out-of-doors. In the abattoir, where it can be assumed that a proportion of sheep admitted for slaughter are tick-infested, infection was probably conveyed by the bite of an infected tick, although the possibility of the virus gaining entrance to the body by infected material contaminating the skin is perhaps worth considering; as might be expected, many of the employees suffer numerous abrasions and cuts.

Vaccination of susceptible personnel in laboratories has been suggested by Edward; and in 3 volunteers given three doses of a formolised mouse-brain vaccine the development of antibodies in high titre seemed to indicate a high degree of protection. Vaccination, however, is not without risk, and in the field at any rate its employment could not be considered without more information about the incidence and morbidity of louping-ill infection in man.

SUMMARY

A case of louping-ill meningo-encephalitis in an abattoir worker engaged in sheep killing and skinning is reported.

Laboratory diagnosis is important in separating this disease from other forms of virus encephalitis giving rise to similar symptoms.

Sera from 38 of the patient's fellow workers were examined for neutralising antibodies against the virus of louping-ill. Such antibodies were definitely present in 3 cases, and possibly present in a further 3.

Serological surveys in the field would probably bring to light cases which have hitherto escaped detection, thus providing a truer picture of the incidence in man.

For the clinical account of the patient's illness before his admission to hospital we are indebted to Dr. Agnes M. K. Culver who suggested at the outset the possibility of tick infection. Our thanks are also due to Dr. W. M. Elliott, *physician-superintendent*, Ruchill Hospital, *for permission to* publish this case, and to Mr. J. A. Rennie, general manager of markets, Corporation of Glasgow, for facilities at the abattoir.

VENTRICULAR FIBRILLATION RECORDED TEN HOURS BEFORE DEATH FROM MYOCARDIAL INFARCTION

W. M. Priest
M.D. Lond., M.R.C.P.
PHYSICIAN, WARNEFORD HOSPITAL, LEAMINGTON

Ventricular fibrillation has sometimes been observed and recorded when occurring for short periods and giving rise to syncopal episodes of the Stokes-Adams type (e.g., Schwartz 1936). But electrocardiographic records of the dying heart are, for obvious reasons, less common, and Hamilton and Robertson (1933) claimed that theirs was the first published. Later Smith (1939) recorded a case in which ventricular fibrillation came on nine hours after coronary thrombosis, and Goodrich and Needles (1940) one in which it came on ten days after occlusion. Thompson in 1941 remarked that very few electrocardiograms had been taken at or near the moment of sudden death from angina and coronary occlusion, and that, though such deaths were usually attributed to ventricular fibrillation or ventricular standstill, little direct evidence was available about the terminal cardiac mechanism. I have been unable to trace any examples published in this country. In the case here reported the electrocardiogram was not taken at the moment of death, which occurred suddenly ten hours later; but the unexpected appearance in the record of a short phase of ventricular fibrillation makes it instructive.

The patient was a woman of 67; she was a hypertensive and had complained of breathlessness on exertion for several

Serological Survey

Rivers and Schwentker (1934) applied neutralisation tests to the sera of four laboratory workers suspected of having had louping-ill; tests were also made on the sera of other people working with the virus as well as the sera of those who had no known contact with the virus. The findings showed that close contact with the virus was associated with the appearance in the serum of neutralising antibodies. Of 7 people who had been in contact with the virus, 5 possessed neutralising sera; and of these 5, 3 had had encephalitis, 1 had been sick with an influenza-like illness, and 1 had not been ill at all. Of 46 people who gave no history of contact, 1 had a weakly active serum. Edward (1948) demonstrated complement-fixation antibodies in 7 out of 12 persons previously engaged in louping-ill vaccine production; all except 1 gave a history of febrile illness consistent with louping-ill.

These observations reveal that infection in the laboratory may be brought to light only by serological surveys. No such surveys have as yet been undertaken in the field, and the discovery of the case of louping-ill described above prompted us to investigate the patient's fellow workers at the abattoir, in an effort to detect unrecognised infection contracted in an occupation involving intimate contact with sheep from known louping-ill areas.

METHOD

Of 38 employees who were questioned, all said that they were familiar with the sheep-tick, but on closer inquiry it was suspected that some were confusing *Ixodes ricinus* with a degenerate blood-sucking insect well known to them as the sheep-ked.

The 38 workers fell into three groups according to the nature of their duties: (*a*) 12, engaged solely in sheep killing and skinning, whose period of employment ranged from fifteen to forty years; (*b*) 23 offal workers who were younger, with no more than four or five years' service; and (*c*) 3 men, with a length of service similar to the offal workers', concerned with the disposal of the blood of sheep and cattle. In each group the work involves constant contamination of the skin by the blood and intestinal contents of sheep; and this suggests the possibility—perhaps remote—of direct infection from sheep actually infected at the time of slaughter.

The majority of the men were of a healthy and robust type. Their medical histories disclosed only a few illnesses, such as pneumonia, rheumatism, and gastritis; and with the possible exception of some antecedent attacks of "influenza" there was no history suggesting infection with the virus of louping-ill. There was no instance of meningitis or encephalitis or of any nervous disease involving admission to hospital.

Blood samples from each of the employees were examined for neutralising antibodies against the louping-ill virus. As controls, similar dilutions of the vir mixed with normal horse-serum and with a neutralising serum. The results of clearly posi are recorded in table III. Of the 38 sera, 2 a the virus strongly, a 3rd, though definitely the virus, was less active, while 3 (not shown in were doubtfully active and were perhaps co with the case reported by Rivers and Schwentker when there had never been contact with the Each of these results was confirmed in a second Of the 3 men with definitely positive sera, 2 (A and belonged to the group of 12 sheep killers and and 1 (C) came from the group of 23 offal A's medical history revealed that during his twent years' employment he had twice had pneumonia and "influenza." His fellow worker, B, during his years' service, had twice had rheumatic fever. offal worker, C, had begun work at the abattoir two years previously, and contracted severe twelve months later when he was confined to bed home for fourteen days. The 3 men with active sera were sheep killers and skinners of more twenty years' experience. With the exception of 1 gave a history of having had influenza some y previously, their medical histories were non-contribut There were no positive sera among the handlers sheep's blood.

Discussion

The case reported here, when compared with o descriptions of louping-ill, illustrates the variations in clinical picture. At first there may be only influenza symptoms lasting about five days and clinically unre nisable as those of louping-ill. The initial illness ma followed, as in our patient, by a second pyrexial p (see figure) associated with symptoms of mild or se meningo-encephalitis. The initial influenza-like ill lasting for five days and followed by involvemen the central nervous system after an intervening afe period is clearly illustrated in the case-reports of Ri and Schwentker (1934), Wiebel (1937), Wesemeier (1 Davison et al. (1948), and Brewis et al. (1949). biphasic temperature reaction is a feature of the di in sheep.

The similarity of louping-ill in sheep to poliomy in man has been pointed out by Gordon (1934). poliomyelitis a latent period may divide two pyr phases, resulting in the so-called dromedary tempera chart described by Draper (1917). An initial "illne infection" has also been noted in measles (Goodall 1 and in mumps (Harries and Mitman 1947). In hu louping-ill this phenomenon is probably a constant fea

Rivers and Schwentker (1934) suggested that primary illness represented a systemic infection, a sheep, and that later the virus attacks the ce nervous system; but attempts to demonstrate virus in the blood and cerebrospinal fluid in 2 of

TABLE III—NEUTRALISING ACTIVITY AGAINST LOUPING-ILL VIRUS OF NORMAL HORSE-SERUM, OF SERA FROM T MEN (A–C) EMPLOYED AT ABATTOIR, AND OF KNOWN NEUTRALISING SERUM

Test no.	Dilution of virus	Normal horse-serum	Serum A	Serum B	Serum C	Known neutrali- serum

	10^{-4}	10, 10, 11, 11, S, S	..	..	..	..

Equal parts of serum and of virus in the dilutions stated were mixed and allowed to stand 1 hr. at room-temperature. They then injected intramuscularly (0·1 ml.) into mice. The numerals show the survival-period in days, of individual mice. S = animal survived.

hich 11,000 were neutrophils. The blood-sedimentation was 63 mm. in one hour (Westergren). As the diagnosis ed to be lobar pneumonia and as there had been no onse to sulphonamides, she was put on to treatment penicillin, 100,000 units eight-hourly. By June 12 was no improvement in the fever and the physical pointed to a right-sided pleural effusion. On June 13 right pleura was aspirated and 10 ml. of dark yellow, tly turbid fluid was obtained. Microscopy showed large bers of pus cells, but because she was on penicillin tment no culture was asked for.

e continued to deteriorate, and on June 15 about 400 of bloodstained fluid was aspirated with some difficulty the right pleura. No culture was made, for the same on as before. On June 16 further X-ray films showed fluid levels at the posterior aspect of the right lower The white-cell count was 13,000 per c.mm., of which 00 were neutrophils. On June 17 she began diarrhœa. June 18 a third chest aspiration was performed and ml. of bloodstained fluid was obtained; microscopy wed autolysed pus cells. Again, unfortunately no culture made.

n June 25 penicillin treatment was stopped. On e 26 radiography showed no change from that of e 16. A blood-count showed hæmoglobin 79% and te cells 10,000, of which 9000 were neutrophils. The blood-imentation rate was 80 mm. in one hour. The patient's eral condition had sadly deteriorated and her appearance gested that death would take place in a matter of weeks, not days. On July 2 the right pleura was aspirated for fourth time and 5 ml. of thick bloodstained pus was tained, from which *S. oranienburg* was grown. On July 4 empyema was drained by a rib-resection by Mr. D. C. rry. On July 5 a urinary culture showed only a slight wth of *Bacterium coli*. On July 6, penicillin, 100,000 its eight-hourly, was resumed. On July 8 *S. oranienburg* s grown from the stools. On July 9 a blood-culture was rile. Thereafter, the patient's general condition improved.

On July 15 a blood-count showed hæmoglobin 82% and ite cells 10,000 per c.mm., of which 7000 were neutrophils. e blood-sedimentation rate was 85 mm. in one hour. pleurogram showed a cavity still containing pus, but the ng itself was more translucent. On July 19 penicillin eatment was stopped, and the patient allowed up from d for the first time. On Aug. 7 another pleurogram owed a much smaller cavity, but a bronchopleural fistula. he returned home on Aug. 19.

On Aug. 20 *S. oranienburg* was again isolated from the eces. Further radiography on Sept. 20 showed that the ronchopleural fistula was still present. The drainage tube as removed on Dec. 15, and the chest sinus healed a week ter. The last stool-culture positive for *S. oranienburg* as on Aug. 20, and the first negative culture on Dec. 15. y May, 1948, the patient was perfectly well, and leading an ctive life.

BACTERIOLOGICAL INVESTIGATIONS

Fæces.—June 7: rectal swab sterile. (The specimen was nsuitable for isolation of pathogens, so the negative result s unreliable.) July 8 and Aug. 20: *S. oranienburg* isolated. Dec. 15: no pathogens isolated.

Pleural fluid.—June 13 and 19: examined for cells only; not cultured. July 2 and Aug. 7: *S. oranienburg* isolated.

Blood.—July 9: culture sterile.

Urine.—July 5: *Bact. coli* isolated.

The salmonella isolated from the fæces and from the pleural fluid was identified by Dr. Joan Taylor, of the Salmonella Reference Laboratory, as *S. oranienburg*. The antigenic constitution was: O = VI . VII

H = m t . . .

The patient's serum on July 9 agglutinated her own organism to the following titre: H, 1 : 1600; O, 1 : 20. The stock strain of *S. oranienburg* was agglutinated to the same titre.

COMMENT

This case is reported firstly because of the unusual infecting agent, and secondly to remind physicians of the occasionally invasive habits of salmonella organisms and that diarrhœa complicating pneumonia requires bacteriological investigation.

In the patient described, treatment with sulphonamides and penicillin was entirely without effect, and the turning-point of the illness was drainage of the empyema. Assuming that *S. oranienburg* was the infecting agent at the beginning of the illness, the organism persisted in the body for at least 82 days, a matter of importance in an ambulant patient.

We wish to record our thanks to Mr. R. L. Vollum, D.PHIL., and Dr. Joan Taylor for the bacteriological observations.

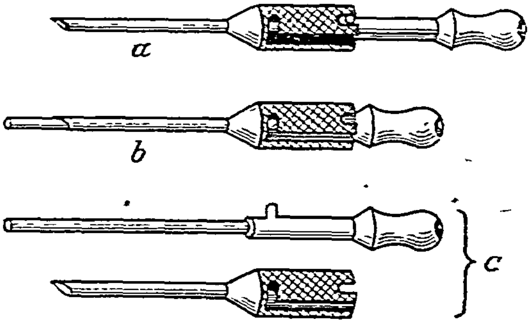
New Inventions

COMBINED INTRAVENOUS CANNULA AND NEEDLE

WHEN a standard blood-giving set is used for intravenous therapy, if the patient makes a sudden movement the needle may pierce the wall of the vein. This results in a hæmatoma in the arm and the needle must be reinserted. An accident of this kind is fairly common when one of the antecubital veins is chosen for the transfusion.

The instrument illustrated below consists of an inner cannula, which is attached to a standard giving set, and an outer needle which acts as a trocar. The needle is attached to a long mount provided with a groove in which a projection on the cannula slides up or down as desired.

The needle is inserted into the vein as in *a* in the accompanying figure. Directly the vein wall is pierced, the cannula is pushed down the groove of the needle until it occupies the position shown in *b*. A lock at the end of the groove and at the top of the mount prevents the cannula or needle from slipping. The cannula and needle can now be pushed well into the vein without damaging its wall, because the end of the cannula projects beyond the sharp point of the needle. The cannula and needle are shown separately in *c*.



This instrument is much easier to insert into a difficult vein than the usual intravenous needle. It also has the following advantages over the other instruments described,[1] in which the needle is inside the cannula:

(1) A syringe is not necessary for introduction into a vein.

(2) After insertion into a vein the needle is not withdrawn.

(3) The needle and cannula can be inserted into a vein with the intravenous apparatus attached.

The instrument has been made to my specification by the Endoscopic Instrument Co. Ltd., Fitzroy Road, Chalk Farm, London, N.W.1., and I would like to thank Mr. F. T. Lowerie for his help in its design and making.

F. R. ELLIS, M.B. Lond.
Assistant Pathologist, The London Clinic, W.1.

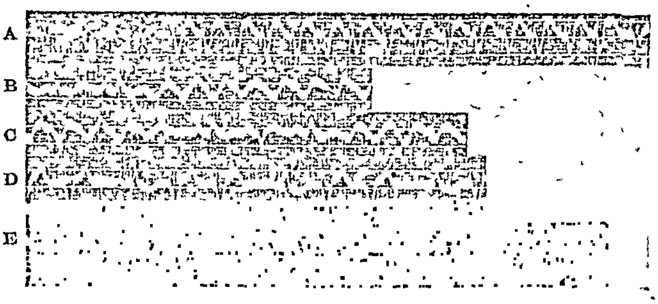
years, with occasional mild anginal pain. For two or three months dyspnœa had been increasing, until it was present at rest and she developed slight œdema of the ankles. Anginal pain became more frequent and severe, and finally her capacity for exertion was reduced to zero. Her medical attendant states that, when he first saw her on Nov. 15, 1947, she showed signs of early congestive failure, and anginal pain occurred after "walking a few steps." The blood-pressure was 240/120 and arteriosclerotic changes were present in the optic fundi. She was put to bed, but anginal attacks, relieved by trinitrin, continued even at rest. On Nov. 26 she had a severe attack of chest pain lasting an hour, which subsided after a dose of morphine, and during the next few days she was thought to have improved slightly. On Dec. 9 her blood-pressure had fallen to 150/110, and on Dec. 14, she had another attack of severe chest pain all day, which again subsided when she was given morphine. No further incidents occurred till Dec. 26, when dyspnœa greatly increased, the pulse-rate was 140 and "was halved by increasing pressure on the cuff." She was admitted to hospital on Dec. 30, 1947.

On admission she was in advanced congestive failure; the blood-pressure was 150/100, the apex-beat was 6 in. from the midline, and the pulse-rate was continually varying from about 110, when it was quite irregular, to 200, when it was regular. The periods at the slower irregular rate lasted only a few seconds and were repeated about every half-minute. No added sounds were heard. The patient was cyanosed and orthopnœic, but distress was not extreme, and she could converse for short periods.



Electrocardiogram: A, lead I; B, C, lead II; D, lead III; E, lead IV.

Electrocardiogram.—At 3 p.m. on the day of admission an electrocardiogram was taken (see figure). All the strips were taken on a single occasion within the course of a few minutes. Lead I (A) shows a phase of ventricular tachycardia following and ending in normal rhythm. Lead II (B) shows the beginning of a phase of ventricular fibrillation; (C) shows two phases of ventricular fibrillation with interspersed normal cycles and an oppositely directed ventricular complex. Lead III (D) shows each normal beat followed by paired ectopic ventricular beats. Lead IV, apex (E) shows two phases of ventricular tachycardia with intervening normal and ectopic beats. The normal beats show elevation of the S.T. segment and a small or absent R-wave, evidence of myocardial infarction. (No digitalis or allied drug had been given before electrocardiography.) The patient died suddenly ten hours later.

Necropsy.—A small pericardial effusion was found; the heart was greatly enlarged and showed an area of infarction on the anterior aspect of the left ventricle about $2^1/_2$ in. in diameter, involving almost the whole thickness of the wall. There was gross narrowing and atheromatous change in the coronary arteries, but no thrombus was found.

In this case electrocardiography confirmed the diagnosis of myocardial infarction and revealed ventricular tachycardia and ventricular fibrillation. The patient survived ten hours after this was first observed.

I am indebted to Dr. W. B. Wallace for details of the patient's condition before admission to hospital.

PNEUMONIA AND EMPYEMA DUE SALMONELLA ORANIENBURG

A. M. Cooke
D.M. Oxfd, F.R.C.P.
PHYSICIAN TO THE RADCLIFFE INFIRMARY, OX.

A. R. H. Williamson
M.R.C.S.
OF NETTLEBED, OXON.

In the enteric group of fevers complications affe the respiratory system are well recognised. A 25 per cent. of typhoid patients have bronchitis at time in the illness (Reimann 1938). Bronchitis, pleu empyema, lung abscess, and osteochondritis of the have all been recorded (Minor and White 1946).

Similar complications in patients with other salmo infections are less common. Seligmann, Saphra, Wassermann (1943, 1946) found 26 respiratory comp tions in 3000 cases of salmonella infection. Respir *infections, ranging from a mild pharyngitis to pneum* with septicæmia have been recorded from *Salmo choleræ-suis*, *S. enteritidis*, *S. kentucky*, *S. new S. typhi-murium*, *S. dublin*, and *S. oranienburg* (S 1934, Harvey 1937, Seligmann et al. 1943, 1946, and White 1946). Of these organisms, *S. cholera* is the most invasive, the most likely to produce monia, and the most dangerous. Harvey (1937) rec among 71 patients suffering from *S. choleræ-suis* infec 24 instances of pneumonia, with 10 deaths. *S. oranie* has been implicated as a cause of pneumonia in recorded instances (Kerrin, Elder, and Smith Jager and Lamb 1943, Seligmann et al. 1943 (one 1946 (two cases)).

This organism also sometimes invades other o and tissues outside the alimentary tract. It has grown from the blood by Jager and Lamb (1943), C (1944), and Partington and Cooper (1948), from gall-bladder or bile by Levine (1942) and Selig et al. (1943), and from the meninges by Seligmann (1943) and Hollis and Barron (1944). It has also found in the appendix and an abscess of the bu by Seligmann et al. (1943).

The following case-report describes a patient had a severe and indeed nearly fatal illness fro *oranienburg* infection of [illegible] tract. indicates some of the [illegible] treatment of the condition.

CASE-REPORT

The patient was a married woman aged 65, livi extremely good economic circumstances and hygienic roundings. She had had no serious illnesses, but had al been liable to minor respiratory infections. No-one el the household had been ill for a matter of months b the patient's illness.

She had returned from a holiday in Switzerland a few before the onset of malaise and cough on May 30, There was diarrhœa for one day, and one sweat. On J she was found to have a temperature of 102·5°F, an subsequent record showed a remittent fever. Her complaint was of fatigue. She was given sulphamera 13 g., over a period of three and a half days with no app effect. In the absence of abnormal physical signs no diag was made, but in view of subsequent events it is of int that the type of fever and her general appearance ca the question of enteric fever to be raised on June 4.

On June 7 she had troublesome cough, followed by at the right lung base. Bacteriological examination rectal swab was negative. On June 8 she complaine right shoulder-tip pain, and physical examination sh signs suggestive of right basal pneumonia. On this also she passed a loose stool.

She was admitted to the Acland Nursing Home, Ox and on June 9 the diagnosis of pneumonia was confir by X rays. The white-cell count was 14,000 per c.

Reviews of Books

Iron Metabolism and its Clinical Significance

A. VANNOTTI, M.D., director of the medical policlinic and professor of internal medicine, University of Lausanne; A. DELACHAUX, M.D., reader in the policlinic. Translated by E. PULAY, M.D. London: Frederick Muller. 1949. Pp. 267. 32*s*.

DESPITE the brilliant isolation of "B12" and the recognition of cobalt and other trace elements as indispensable to life, iron remains in the centre of the stage so far as mammalian respiration is concerned. Its absorption, transportation, and excretion, its two forms of oxidation, and its multiple rôles in cellular metabolism are none of them fully understood, and any thoughtful review of the subject must be reckoned as a valuable contribution to our knowledge of metabolism. This Swiss book has an outlook not limited by our own horizons of language and approach. After reviewing the absorption, excretion, and storage of iron and the various forms in which it occurs in the body, the authors discuss their own findings in a study of the various fractions of serum iron and the non-hæmoglobin iron in the other parts of the body. They separate the serum iron into four fractions, which (they are careful to point out) were not necessarily present as four different chemical compounds in the circulating plasma but which nevertheless undergo considerable individual variation under different physiological and pathological conditions. The methods of separation are given and the relation of each fraction to previous findings is considered in some detail. There are also many experimental data which cannot be summarised, having been acquired by a study of normal men and women at low and high altitudes, patients with anæmia, liver disease, and many other pathological conditions, and experiments on animals.

The book contains 11 diagrams and a considerable number of tables. The bibliography is satisfactory but not exhaustive, and there is a subject and author index. Being clinicians at heart, Professor Vannotti and Dr. Delachaux end with a chapter on the practical aspects of iron therapy; but their book will probably be of more value to the investigator than to the practising physician. The text has probably lost something by translation, for some of the sentences are long and involved, and the sense is not always crystal clear. The translation of a book of this size, however, from German into modern scientific English was a task which few would have been able to undertake, and Dr. Pulay is to be congratulated rather than criticised for his labours.

Red Cross and St. John War Organisation 1939-47

P. G. CAMBRAY; G. G. B. BRIGGS. 1949. Pp. 723.

The Red Cross and the White

A short history of the Joint War Organisation of the British Red Cross Society and the Order of St. John of Jerusalem during the War 1939–1945. HILARY ST. GEORGE SAUNDERS. London: Hollis & Carter. 1949. Pp. 195. 8*s*. 6*d*.

"Almost everything that a prisoner in Axis hands ate and everything he read and wore had to be provided through Geneva." This remarkable statement is the key to the story that Mr. St. George Saunders tells in his short history, and is one of the best justifications for the perpetual neutrality of Switzerland. His book is an epitome, which anyone may purchase, of the larger reference work, by Mr. Cambray and Mr. Briggs, which is not on sale. On Sept. 2, 1939, a formal agreement was reached between the British Red Cross Society and the Order of St. John of Jerusalem to establish a Joint War Organisation to carry out, in collaboration, their relief work during the coming war. The reference volume records, in considerable detail, the amazingly widespread activities of this joint body. The careful record that had been left of their joint work during the 1914–18 war enabled the organisation to start, to a great extent, fully prepared. The original design of the Red Cross, to ameliorate the conditions of the wounded and sick in the field and to ensure for prisoners of reasonable treatment, was never lost to view, and book shows to what extent under conditions of warfare these principles can be applied.

For all prisoners life would have been grim if it not been for the food and clothing sent them under auspices of this organisation; but it is in such things the care and training of the blinded, and the provi of occupational therapy, the arrangements for send seeds of vegetables and other plants to prisoners th the organisation's wide conception of humanity recognised. Over a quarter of a million books were supplied to prisoners, and over 100 allowed their examinations to be conducted in p of-war camps. The care of the prisoner began was first notified as captured, and did not end until was safely repatriated. This did not apply only members of the Armed Forces: civilians who we interned in camps, or who were "detained" in remot villages, under a form of "house arrest," came und the care of the organisation. The value of the voyages of the *Vega*, loaded with necessities, from Lisbo to the Channel Islands, cannot be overestimated. home the organisation took a prominent part in supplyi staff for Civil Defence, and in all activities resulting fro air-raids—evacuation, shelters, rest-homes, and the li In collaboration with the Ministry of Health it establish a series of residential nurseries over the country.

After the end of the war the Joint Organisation d much in the camp at Belsen, and gave help to t hordes of displaced persons, and to the Germans, s shocked and despairing after their collapse. The work the International Committee, composed entirely of Sw is well explained, and the policy of building up l stores in Geneva is seen to have been fully justifie

Both books show what a large part can still be play by voluntary effort in a total war, and many will rec that the work of these two great and similar bod should not be united also in times of peace.

The Mental and Physical Effects of Pain

(Buckston Browne Prize Essay, Harveian Society, London, 1948.) V. C. MEDVEI, M.D., M.R.C.P., associa chief assistant, endocrine clinic, St. Bartholome *Hospital, London.* Edinburgh: E. & S. Living-to 1949. Pp. 59. 3*s*.

THE study of pain is in the forefront of present-d medicine, and much detailed experimental and clini work on it has been done. Original accounts of t subject as a whole have been rare, however, and those pu lished are in the main summaries of the authors' person fields of experience. In 1948, the Harveian Society London set "The mental and physical effects of pain as the subject for the Buckston Browne prize ess The prize-winning essay appears in this booklet wi only slight modifications. Although a few person clinical observations are given, Dr. Medvei's chi concern has been to offer a critical survey of our prese knowledge. His success is well attested by t award.

Blakiston's New Gould Medical Dictionary (Ph adelphia and Toronto: Blakiston. 1949. Pp. 1294. $8 50 —*Gould's Medical Dictionary*, after reaching five editions fifteen years, has changed its title and editors, the new edit being Dr. Harold Wellington Jones, Prof. Normand L. Ho and Mr. Arthur Osol, PH.D. This work, they say, thou based on its predecessor, is a completely new reference boo and it is certainly impressive, with clear type and first cl illustrations, many of them in colour.

Textbook of Surgical Pathology (6th ed. Londo J. & A. Churchill. 1949. Pp. 726. 45*s*.).—The new editi of this good book by Prof. C. F. W. Illingworth and Dr. Bru M. Dick has been generally revised. The sections on thromb phlebitis, brachial neuritis, sciatica, peptic ulcer, splen anæmia, and intestinal obstruction have been rewritten, an fresh matter includes descriptions of vascular hypertensio causalgia, and tumours of muscles. A new chapter has be added on diseases of the pericardium, heart, and great vesse The illustrations too have been revised and augmented, b the book has kept its original convenient size.

THE LANCET

LONDON: SATURDAY, OCT. 15, 1949

R. H. B. (49) 132

SLOWLY but steadily the regional hospital boards working their way through the task of coördinating l reorganising the hospitals into a coherent service. ich time and effort have been required for the uping of hospitals into administrative units, the mation of management committees, the survey of st function and future need. and the assessment and ssessment of status for the professional staff. ence it is not surprising that few final decisions ve yet been taken or authoritative statements made the functions and establishments of individual spitals. But if authority has been silent, rumour is been commensurately noisy in proclaiming far-aching changes for all. Special hospitals of long pute are to be swallowed by some neighbouring viathan; full-time staff are to be recruited for ospitals hitherto well served by part-timers: the eneral practitioner is to be excluded from all association with his hospital: and the cottage hospital is o vanish from the land. So run the rumours. Not ll are believed; not all are true; but there is enough ruth in them to justify discontent and anxiety.

Into this troubled arena the Minister of Health as now stepped. His circular letter (R.H.B. [49] 132). hich we publish in full on p. 711, is a document of ignal importance, stating principles that boards hould bear in mind when considering changes in he use of hospitals. Happily. few irrevocable changes have yet been made and the boards will still be ble to review their hospital policy in the light of hese new recommendations. The emphasis now is n the need to avoid loss of service to patients or nnecessary disturbance of medical staff. The value f local loyalty to the local hospital should not be verlooked in weighing the advantages of reorganisaion, and proposed alterations should be discussed with the people most concerned. In particular the Minister examines the disadvantages to be expected from radical changes in the staffing or function of ottage hospitals and the like, where beds have been n the care of general practitioners. Admitting that n the past some of these hospitals have done work for which they were unsuited, and agreeing that the present opportunity should be taken for associating visiting consultants with them, he nevertheless sees a continuing need for hospitals "to which the general practitioners of the neighbourhood can admit patients who require treatment within the scope of a general practitioner but who, for various good reasons, cannot be treated at home."

> "It is, in the Minister's view, very valuable for the general practitioner service of the district when the family doctor has access to beds where patients of this type can be in his charge. and he knows he can readily call upon the services of a consultant for a second opinion, and it is essential if the level of general practitioner medicine is to be maintained that the interchange of ideas between general practitioners and specialists should be facilitated by such consultation and by informal contacts on the occasion of regular visits from consultants to general practitioner hospitals."

So high does the Minister rate these needs that he suggests that in places where cottage-hospital beds now have to be put to other special use—"e.g., as a maternity unit. a recovery hospital, or a geriatric unit"—other beds in the district (perhaps in a "general practitioner wing" of the district hospital) should be placed in the local practitioners' charge. In view of the known tendency of many of the regional boards to staff the smaller maternity units entirely from hospital obstetric departments, it is heartening, too, to note his insistence that general-practitioner obstetricians should still be given the charge of maternity beds, with the obstetric resources of a larger hospital at their back. As a supplementary means of associating the general practitioner with the work of the hospitals, the Minister recommends the creation of clinical assistantships tenable by general practitioners, in which they could become part of a team in the district general hospital. But there would probably not be very many appointments of this type, and they should not, in the Minister's view. be regarded as a substitute for putting beds at the general practitioner's disposal.

Obviously it will be impossible for boards to apply in every type of area the policies outlined in this memorandum. In industrial and urban areas served chiefly by large hospitals which already have an ample establishment of resident and visiting staff, the provision of general-practitioner wings will be resisted and retarded. (Actually, until the size of practices in such areas is reduced, few practitioners will have much time to give to the care of their patients in hospital.) But in the smaller towns, and in the countryside, the situation is quite different, and doctors here will particularly welcome the Minister's plea that their association with their hospitals should not be unnecessarily disturbed. Eventually, we believe, the regional boards will themselves look back on this circular with approval. They are now responsible for providing a specialist service that will almost everywhere need extension; yet few of their hospitals which are remote from cities or university centres have ever had enough staff of full consultant status to meet the needs of their patients adequately. With growing demands, particularly for outpatient and domiciliary consultation, the boards are almost sure to find many gaps to fill, even when they have made use of all the consultant talent available in their areas. These gaps cannot all be filled satisfactorily by men of registrar grade, partly because these men—the consultants of the future—should have their training mainly in centres where they can work under and learn from the best teachers, and partly because to multiply registrarships out of all proportion to the numbers of full consultant posts eventually available would be unjust and shortsighted. In these outer areas much of the consultant work in hospital and home has been done in the past by men who were also in general practice. The Minister's circular, coming at this time. may encourage boards to make

Introducing

'DISECRON'

Compound Injection of Oestrogen and Progestogen for the simplified treatment of SECONDARY AMENORRHOEA by the unconventional

2-DOSE TECHNIQUE

ORIGINATED BY ZONDEK

(Zondek J.A.M.A. *118*, 705, 1942)

PRESENTATION

Sterile solution in oil for intramuscular injection containing in each c.c. 12.5 mg. progesterone with 2.5 mg. oestradiol benzoate. Ampoules of 1 c.c. in boxes of 2, 10 and 25. Vials of 10 c.c.

'ETHIDOL'

(Ethinyl Oestradiol)

A British Schering preparation of this potent orally-active oestrogen is available under the convenient name "Ethidol".

Ethidol is presented as tablets of 0.01 mg. and 0.05 mg. in bottles of 25, 100, and 500.

Literature gladly supplied on request

BRITISH SCHERING
LIMITED
LONDON

'VOLPAR'

TRADE MARK

VOLuntary PARenthood

A report (Human Fertility, Vol. 6, No. 1, p.1) upon the times taken by fifteen different chemical contraceptives to effect complete immobilisation of spermatozoa demonstrates, clearly and decisively, the effectiveness of 'Volpar' preparations; indeed, the results of the investigation proclaim the supreme position held by 'Volpar' when classed according to its spermicidal activity. Moreover this classification is reflected in the confidence placed in 'Volpar' Gels and in 'Volpar' Paste, both in the clinics and by the medical profession.

A specially designed 'Volpar' Applicator is now available for those patients who prefer to use 'Volpar' Paste instead of 'Volpar' Gels.
For maximum safety 'Volpar' Gels or Paste should be used with a cap or sheath.

Specimen packings of 'Volpar' Gels or Paste will be forwarded to physicians on request.

MEDICAL DEPARTMENT
THE BRITISH DRUG HOUSES LTD. LONDON N.1
TELEPHONE: CLERKENWELL 3000
TELEGRAMS: TETRADOME TELEX LONDON
VOL/E/26

1939, except that the manufacturers' applications ow dealt with quickly by correspondence instead the necessarily infrequent meetings of a large of experts. The complaint, which GREEN[5] tions, that official clinical trials involved a great of delay, has thus been largely met. This was reason why the T.T.C. was allowed to lapse; her was that even before the war the committee become impracticably large, and it would have to be bigger still to deal with the rapidly expanding of modern therapeutics.

o submit all new drugs which pass their "preical" tests to an officially supervised, fully conled clinical trial before they are put on the market o doubt an unattainable ideal. Moreover, statistical of, if it is obtainable at all, often requires years bservation; and, as LEAKE and others[6] pointed it is as wrong to postpone the use of a promising edy as to apply untried agents prematurely. So re will always be some new remedies whose general ease is justified on pharmacological or other grounds ich would not satisfy the statistician. The Medical search Council's aim is to organise tests of a tentially valuable new drug (or an old drug in a w application) whenever this seems to be in the blic interest, whether or not the manufacturer has ked for them. Only a small proportion of the drugs ued are judged worthy by this criterion, and it is official body's business to scrutinise the remainder. ould it not be a great help to the practising doctor there was something on the lines of *New and on-Official Remedies* over here with a M.R.C. comittee to approve or disapprove of any new drug, owever uninteresting, on the evidence submitted by e makers? The N.H.S. provides a good reason r such an innovation.

Lessons from Plaster

TETANUS still arises in the classical way, from wound contaminated with infected soil; but in ost of the cases reported nowadays from all parts f the world the sources of infection would have een thought bizarre fifty years ago. KOCH incriminated the surgeon's catgut as long ago as 1898,[7] nd since then low-grade cotton-wool (used as padding or splints),[8] woodwool (in gynæcological pads), and ther ineffectually sterilised dressing materials[9] have een shown to harbour *Cl. tetani*. The latest example s in Canada,[10] where the application of a plaster cast fter arthrodesis of a tuberculous knee was followed y fatal tetanus. *Cl. tetani* and *Cl. welchii* were ecovered from the operation wound at necropsy and rom an unused plaster bandage of the same make as hat used by the surgeon; no tests are reported on he other dressing materials. A coöperative inquiry by other hospitals and the Department of National Health and Welfare at Ottawa showed that plaster bandages from fourteen manufacturers rarely contained *Cl. tetani* but were almost invariably contaminated with other clostridia, especially *Cl. welchii*. War experience with tetanus toxoid has shown that more nearly perhaps than can be said of any other disease, deaths from tetanus are avoidable.[11] But a disease which kills on an average only 6 persons per million per annum in this country is not going to excite a very vigorous campaign for active immunisation in peace-time. The alternative—the sterilisation of all materials likely to contaminate an open wound —presents the classical difficulties associated with the destruction of a spore-forming micro-organism. Dressings and bandages can be, and almost always are, sterilised successfully in the autoclave, but the water vapour is ruinous to plaster-of-paris. Dry heat, which is seldom a satisfactory substitute, if it is to sterilise a rolled bandage right through must reach such a temperature for such a period that it is likely to char the fabric. Exhaustive trials by the Canadian workers suggest that a temperature of 190°C for 90 minutes kills all clostridial spores, but some plaster bandages were rendered useless in the process. No doubt the makers of these products will carry the investigation further. No attempt was made, it seems, to discover whether the clostridia entered the finished bandage in the plaster or in the fibrous matrix; paper, which is commonly used as a matrix, seems the most likely source. It should not be impossible to sterilise both plaster and matrix before incorporation in the bandage, and reasonably aseptic methods of manufacture and an occlusive packing should then avoid extraneous contamination. The indignant surgeon will ask why, if his plaster bandages so commonly contain clostridia, his wards are not teeming with cases of gas-gangrene and tetanus. One of the lessons of war surgery was that even rather crude bacteriological methods show clostridia in many—say five—times the number of wounds which develop clinical gas-gangrene. These organisms are what the rock gardener would call "miffy subjects," and unless the soil is exactly to their taste they will not multiply. One of the objects of the full exposure of traumatic injuries has been the conversion of a deep wound, fertile ground for clostridial growth, to a superficial one in which these organisms do not flourish. Debridement has much in common with the use of the hoe.

The disturbing feature of mishaps such as this is that contamination is not suspected until it has caused serious infection. Eternal vigilance in the preservation of asepsis is the only way to prevent occasional disasters. But chinks in the armour of asepsis are still to be seen in the practice of nearly every hospital. Untold and often unappreciated labour is expended by manufacturers and pharmacists to ensure the sterility of fluids for parenteral administration, and great care is devoted to the production of "pyrogen-free" water; yet in spite of explicit warnings the bowl of "sterile" water still stands uncovered in the operating-theatre. Dressings for ward and theatre are made up in any convenient corner and put in a drum; the drum is sent to be sterilised and on its return is assumed to be free of infection. In how many hospitals are the sterilisers inspected by a responsible officer; how many use "tubes témoins" among the dressings; how many check the purity of the water used in the theatre? In 1945 the Medical Research Council published an more use of the tried services of these men, and at the same time to create posts where, as clinical assistants, a new generation of general practitioners can find opportunity to take their share of hospital duty. If in addition the circular leads to general practitioners being given a better chance to care for some of their patients in hospital with proper diagnostic and nursing help it may mark a turning-point in the history of the National Health Service—the first practical step towards that restoration and reorientation of general practice which should now be one of our principal aims.

Therapeutic Trials

THAT judgment is difficult and experience fallible is a piece of wisdom familiar enough. Yet most of us turn a blind eye to this axiom when examining the claims for new drugs, whether these take the form of a paper reporting "significant results" or are made in the more fulsome statements that litter the doctor's breakfast table. The National Health Service has been in operation for over a year, and appropriate committees are beginning to discuss some of the consequences of this uncritical attitude. Cramping restrictions officially imposed on prescribing would be highly undesirable, but such restrictions are invited by the casual prescribing of expensive remedies of doubtful therapeutic advantage. An instance is the use of blunderbuss anti-anæmia remedies, the comparative costs of which in the U.S.A. have been discussed by WINTROBE.[1] But whether a doctor should adopt a new drug or new preparation is a question involving far more than the saving of N.H.S. funds; the answer will often determine the patient's chances of recovery.

Large numbers of new drugs appear on the market; how is the practitioner to know whether they are all they are said to be? Have satisfactory trials been made? Sometimes the answer is clearly Yes, but often it is equally clearly No. As long ago as 1905 the American Medical Association founded its Council on Pharmacy and Chemistry to examine the claims made for therapeutic agents; and SOLLMAN,[2] in 1913, reviewing its work, spoke of the difficulty which even "the trained scientific worker may find in distinguishing truth from falsehood, much more so the general practitioner." This is still truer today, when the practitioner may be assailed with specialised information (e.g., in biochemistry and hæmatology) which, if assiduously reiterated, is bound to impress him, whether it is sound or not. Nobody wants to discourage the commercial research which has produced many of the most useful drugs introduced in the last thirty years, but this research might well be stimulated by more planned trials of promising drugs. The arrangement of a satisfactory clinical trial is never easy and may be very difficult. The efficient scheme proposed by VAN WINKLE and others[3] for large-scale investigations has been criticised as too exacting; but its critics agreed on the need for a clear and as far as possible foolproof trial. At present, however, much of the clinical testing of drugs is done by clinicians at the request of the manufacturers arrangement suits the parties immediately for the clinician is glad to make observations publish, and the manufacturer brings a product to the notice of the profession with least possible delay. Much valuable work is this way; *and where, as often, the trials are* by experienced observers, there is no serious for criticism. On the other hand, it is obvious inadequate trials plus enthusiastic advocacy by makers sometimes lead to the uncritical of drugs by many of our profession, who have time to study the evidence in detail even if it objectively presented to them. They can trust in manufacturers who have proved in the past, regretting, perhaps, that so few of trials bear the hall-mark of the *Medical* Council or other unbiased body.

The official mechanisms for the trial of new differ considerably in the U.S.A. and in The A.M.A.'s Council on Pharmacy and whose expert members work voluntarily, with full-time secretary, admits "acceptable" products its *New and Non-Official Remedies* after assessing evidence submitted by the makers and others making inquiries of its own. The whole process take 6–10 weeks, or less in an emergency. does not signify approval, but it does imply that drug has conformed to the council's standards *has genuine therapeutic merits.* Since 1946 the council has had its own *therapeutic* trials committee, responsible for organising impartial clinical trials, especially of new drugs[4]; this committee does not direct the methods to be followed but insists on certain conditions being complied with and may offer advice, and it reviews the work done before publication. In Britain the official supervision of clinical trials is a task of the Medical Research Council. Its standing Therapeutic Trials Committee, founded in 1931, has not been reconstituted since the war, and the council now follows three different procedures for different classes of trial:

1. For products of great potential value, such as penicillin or streptomycin, the council appoints a *special committee* of specialists, including a statistician, to organise tests on its behalf.

2. Alternatively, an *informal conference* may be called to plan tests and meet at various stages of their progress. Unlike that of the special committee, the membership of the conference may vary, so that anyone whose advice would help at a particular stage of the inquiry may be invited to attend.

3. When manufacturers apply to the council for clinical tests of a new product they are asked to provide particulars, including the chemical formula where this is known, and details of the pharmacological and toxicity tests on which the expectations of its therapeutic usefulness are based. These particulars are then sent to *expert referees,* who themselves carry out or direct clinical tests of the product if they are sufficiently impressed with its possibilities. The investigators' findings are shown confidentially to the manufacturers before being submitted to a journal for publication as "A Report to the Medical Research Council." Of the dozen or so definite applications for trials received every year, the council deals with about half in this way.

The third procedure closely resembles that followed by the Therapeutic Trials Committee between 1931 solved, even in America. Messages there are given, newer hospitals, by loudspeakers near the nurses' m, and there are often telephones between nurse patient.

. Ward bases his account mainly on British hospital ice in about 1939, since when of course no building large scale has been done. But big arrears of con- tional work must soon be undertaken if the general of hospital practice is to reach that prevailing ad, and many hospital planners are seeking guidance. dicta of the report of the departmental committee he cost of hospitals, published in 1938, and now out uch with modern developments, loom too largely hese pages. Much of Mr. Ward's material is, and ys will be, fundamental to the building of any ital, but something more about the future proba- ies of hospital form, structure, and arrangement ld have been stimulating from one who is so highly rmed.

RESISTANCE OF TUBERCLE BACILLI TO STREPTOMYCIN

HE resistance to streptomycin of a strain of *Myco. rculosis* is now believed to be the result of selection, ing the patient's treatment, of mutants which were ady present in the original bacterial population. ough the proportion of resistant mutants in a popula- n of sensitives has been estimated at less than 10 per ,000 billion they may be forefathers of a resistant e. Streptomycin no more produces drug-fastness n a carving-knife produced a breed of Manx mice. sistance appears when the innate properties of the tant favour its survival and multiplication in an vironment which becomes intolerable to its sensitive lows. If resistance to streptomycin is thus undirected d spontaneous it is important to know whether it curs, in a significant degree, among tuberculous tients who have never received the drug. Youmans d Karlson[1] found that over 90% of 131 strains of *yco. tuberculosis* from untreated patients were inhibited less than 2 μg. of streptomycin per ml. of medium, d in this issue Dr. Mitchison, examining 205 strains om 124 patients before treatment, finds a remarkably iform susceptibility to the drug. These results must e set against such reports as that of the streptomycin ommittee of the American Veterans Association in 1948 hich showed that 60% of cultures from patients who ad been treated for three months were resistant to 0 or more μg. of streptomycin per ml.

Mitchison has now examined nearly 400 resistant trains from treated patients and he finds that the strains all into three groups, each with a characteristic degree f resistance. The organisms obtained from individual atients showed an abrupt change during treatment rom sensitivity to one or other of the levels of resistance, nd when this level was reached it was maintained throughout treatment. This agrees with the view that changes in sensitivity do not occur by any Lamarckian process of training. One group of organisms was found by Mitchison to be only four times less sensitive than that of the standard strain of *Myco. tuberculosis*, and it is obviously important to know whether the concentration of streptomycin in the patient's lesion is sufficient to deal with these slightly resistant strains. Our present relatively crude sensitivity tests may not always detect such small degrees of resistance, and this may account for some of the failures in treatment when the infecting strain has been reported as sensitive.

The problem of streptomycin-resistant strains of *Myco. tuberculosis* is also being tackled from the prevention angle. It was shown in 1946 that the development in vitro of resistant strains could be retarded by adding diaminodiphenylsulfone to the medium, and Graessle and Pietrowski[2] found that *p*-aminosalicylic acid (P.A.S.) acts in the same way. Karlson and others,[3] at the Mayo Clinic, have now done periodic sensitivity tests on cultures of tubercle bacilli isolated from 14 patients being treated with combinations of streptomycin, P.A.S., and promin. At the end of three months of treatment streptomycin-resistant tubercle bacilli were found in only 1 case, although after six months' treatment 3 additional cases also had resistant strains. These are encouraging if only provisional results, and it may well be that streptomycin and P.A.S. or some other form of combined therapy will keep the resistant mutant in his numerical place.

RULING THE WAVES

ADVERTISEMENTS are so much a part of our daily lives that very few, however detached, can be unaware that permanent waving at home by a "cold process" is a matter of interest to many.

Astbury and Bell[4] have shown that keratin—of which hair is largely composed—is one of a group of fibrous proteins with a common molecular pattern and elastic properties. The structural unit of the group is a grid whose main chains are drawn into a sequence of folds; when the fibres are stretched the grid is extended, but when the tension is released it returns to its folded arrangement. Although the analogy is not complete, those who are not chemists can best understand the process by thinking of a lazy tongs in the positions of closure and complete extension. Without moisture the human hair cannot be stretched, and under tension it snaps. If, however, it is dried in a stretched condition little or no contraction takes place. This physical property is the basis of what the hairdressers term a "water-wave." Harry[5] has explained that if the temperature of the wetting agent is increased and the liquid made sufficiently alkaline, a chemical reaction takes place; the elasticity of the hair relaxes, and new and somewhat unstable links between various polypeptide chains form which tend to hold the hair in its new position. A stage may be reached when the alteration is "permanent" and cannot be completely reversed. This property is exploited in many types of "permanent waving." Sebum and dirt are first removed by shampooing; the hair is wound round rollers; a strip of material moistened with a suitable solution is wound round each curl, which is then encased in a heating device; and the hair is "steamed." Harry has found that the most satisfactory permanent-waving solutions contain ammonium hydroxide with borax or sodium (or potassium) carbonate. After the "perm" is completed, the curled hair is wetted, rearranged, and dried, a water-wave being thus superimposed on the permanent wave.

Methods of waving the hair which do not require the use of a cumbersome heating apparatus usually depend on the action of an alkaline reducing agent—commonly a thioglycolate. The hair is wound on to suitable rollers or "curlers"; the agent is applied for a time and then neutralised—and the wave fixed—by an oxidising agent, which sometimes is potassium bromate. One type of solution contains approximately 6% ammonium thioglycolate in water adjusted to a pH of about 9·6.[5]

The hazards of home permanent waving are fourfold. First, owing to inexperience the user may place her curlers in the wrong positions and be vastly disgruntled with the results. But greater disasters are possible. If the waving solution is left to act too long, or is not properly neutralised, or is used too often, the hair may become devitalised, and a day or two later, when combed, the treasured curls—like the proverbial cup-handle—come

admirable pamphlet[12] on the care and sterilisation of syringes. The recommendations seem to be faithfully followed in V.D. departments, but they are still not adopted in all general wards. There are two ways, perhaps, in which these chinks may be sealed. First, since dressings and the like will in future be increasingly bought in bulk, the Ministry of Health might insert a clause in the specifications demanding freedom from clostridial spores. Secondly, a "purity squad" should be an accepted part of the organisation of every hospital.

Annotations

WORLD MEDICAL ASSOCIATION

THIS association has been holding its third annual assembly in London this week, at B.M.A. House. On British initiative it was founded, after the war, to promote closer ties among national medical associations and the doctors of the world, and membership is open to such associations. Forty-two countries now belong—the national associations of two of them being admitted last Tuesday—and twenty-nine of the members have sent delegates to the present assembly. There are no delegates from Bulgaria, Hungary, and Poland, and the president of the Chinese Medical Association, Dr. John Yui, has been unable to attend. At the opening of the assembly, the retiring president, Prof. Eugène Marquis (France), spoke of the strength of the organisation, and referred to the Code of Geneva—a modern version of the Hippocratic Oath drawn up and adopted at the last assembly—as "this code which we hope will bring to the same standard the medical ethics for all nations who favour the cult of liberty." This year's president is Dr. Charles Hill, secretary of the British Medical Association.

The inaugural meeting agreed that a further study should be made of the status of the medical profession, particularly in relation to medical man-power, membership of national associations, and the economic status of the medical practitioner, including his standard of living and how this compares with that of other professional persons. The assembly was also in favour of studies on pharmaceutical practices and on hospitals; investigations already undertaken include those on social security and allied subjects, and on postgraduate medical education and specialist training. A conference is to be called for the coordination of scientific medical organisations, provided enough are interested: Dr. T. C. Routley (Canada), as chairman of council, explained that the idea was that through the W.M.A. such organisations could express their views to governments. Dr. Routley also referred to the value of exchanging medical journals, not only for providing information but also as an inspiration for future activities. The council has agreed that countries in the sterling area shall, for a time at least, continue to pay as subscriptions the amounts of their own money which they would have paid before devaluation—a provision which the Australian delegate, Dr. L. Llewellin Davey, described as very generous. The assembly passed a hearty vote of thanks to the American Medical Association and the United States committee of the World Medical Association. This committee raises funds in the United States which have enabled the W.M.A. to meet its initial running costs, and it is an indication of the interest taken in the association by individual U.S. doctors that they subscribed 12,000 dollars during the first six months of this year, the rest coming from other sources.

Observers from a number of outside bodies have attending the assembly. These include [illegible] from the World Health Organisation of the Nations, to which, it is stated, the World Association bears the same relation as does the B to the Ministry of Health—or nearly the same.

HOSPITAL FITTINGS AND DESIGN

IN these days of mental and material mass [illegible] Mr. Ronald Ward[1] holds no brief for standardis[illegible] hospitals or of their major components; as an ar[illegible] his view is that "ideally every hospital building [illegible] be a skin or shell that will change or grow as the organism within it changes and grows." These large complex structures are still so experimental that are not ripe for attempts at standardisation: a hospital of any size is still an object of internatio[illegible] interest and curiosity. One such standard, which Ward endorses, is that wards must have maximal [illegible] exposure, and that their windows must be as large [illegible] possible; but this fixes the aspect of the hospital within a small compass range, and defines the format of a large part of its buildings. In other countries in similar latitudes it has been found that the patients' average st[illegible] in an acute hospital is about three weeks, that really [illegible] people actively dislike strong [illegible] that the aspect of the wards in this respect m[illegible] than is usually thought. If the southerly fixation-complex could be sublimated to some extent, perhaps the flexibility and compactness of hospital design could be materially improved. The principle of "reason in all things" should also be applied to the ward windows, and the specific planning of at least two single rooms with [illegible] north aspect in each nursing unit is not amiss.

The departments of most importance to the patient—and he sometimes gets forgotten in hospital planning—are those for outpatients and inpatients. Mr. Ward advocates the very proper policy that the outpatient department should be mainly consultative; he might have added that its chief economic function is to keep patients at their work and out of the hospital beds. Something about the provision of comfort for the waiting patient and his relatives would have been welcome in his book, with a few words about perambulator parks, the care of children while their parents are being examined, and architectural treatment to alleviate the station-like dreariness of many outpatient halls and waiting-rooms in British hospitals. It seems likely that the ward unit formed of a number of small sick-rooms has come to stay for some time, and Mr. Ward might well have discussed the structural and administrative implications of this change more fully. These small rooms permit the housing of both sexes within the same unit, thus simplifying many admission problems. The growing practice of getting patients out of bed as soon as possible is driving home the need for more than 2 water-closets to each 25–30-bed unit; moreover as the number of beds in a sick-room—and therefore the size and cubic content—decrease, it becomes more desirable to avoid the use of the bedpan in it. The long-established custom of placing water-closets on the outside wall is also due for reconsideration; if they are transferred to the inside wall and given adequate mechanical ventilation, the ward- can be planned more compactly, with corresponding advantage to the nursing staff, and the greater freedom of design is possible. Double swing-doors should have no place in ward units and have disappeared in most modern hospitals outside this country. In the ward kitchen small mechanical dishwashers should be a usual fitting, like refrigerators. The problem of removing garbage from ward units except by man-power seems to

THE LONG-STAY PATIENT

STANLEY J. FIRTH
M.D.Manc., D.P.H.
YSICIAN-SUPERINTENDENT AND MEDICAL DIRECTOR,
BRIGHTON GENERAL HOSPITAL

e term "chronic sick" is so vague and so difficult ine that some other would be better: and I would st that the whole range of this class of patient be d "long-stay" and not chronic. It is obvious those making up the total include many medical ories, some of which are set out below.

TUBERCULOSIS AND CANCER

ses of Tuberculosis.—These are already tackled ately, and the combination of clinic, chest unit, torium, and mass-radiographic unit should produce lesired result in due course. The question of infec- is receiving attention, and the early diagnosis and val of patients from the general population should n the incidence of further infection, besides offering best prospects of cure to the sufferer.

ses of Malignant Disease.—Malignancy, the most d killer of mankind in the present age, also deserves e tackled as an individual problem. If infection was ature of the illness an effort would probably be made lar to that made for tuberculosis. Cancer is so espread that patients must be treated at the outset cute units; many go on to long-stay units, chiefly symptomatic treatment. Probably we need fairly e special units where concentrated and specialised tment can be given. It should be possible to select ients for admission to such units by answering the ple question "It it cancer or not?" Admission to h a specialised unit should be a boon and comfort to sufferer, for the public are already "cancer-minded," l the mental state of a patient cannot be improved inactivity and bluff. It is far better, surely, to offer atment in a big way.

THE OTHER PATIENTS

With these two medical categories disposed of, what er groups of long-stay sick remain? Who shall care them, and where?

I suggest that the term long-stay patient should be plied to those who are not likely to be less than six onths in hospital. All patients who can possibly be red within six months, and also those who, within at time, can be sufficiently relieved for them to return normal and usual employment should go to acute its.

Senile Cases.—The physical age of human beings nnot be defined entirely by the age in years. Many the 70–80 age-group are physically and mentally etter than some in the 65–70 age-group; and the easons must be sought by careful study of both indi- iduals and groups. By proper organisation of patients n this geriatric group the stage of physical and mental eakness with double incontinence may be avoided or delayed. Those who reach this penultimate stage can only receive nursing care, and should therefore be housed in long-stay annexes where this can be provided.

Elderly Long-stay Sick.—Various conditions can affect the elderly; this group will include people *over 55 years of age* suffering from all types of ailments, and whose recovery-rate is retarded. Apart from malignancy, which has already been mentioned, chest troubles probably claim the greatest number of victims, with cardiovascular diseases second.

The elderly are prone to the same diseases as the young, but their resistance is often diminished and their condition likely to be aggravated by repeated attacks of their "seasonal" trouble. Thus, at some stage, their illness is likely to become more protracted, and the time when they become classified as chronic sick is a matter of chance. Some acquire the label when they should really be eligible for treatment as acute cases, simply because it is known that their convalescence is likely to take longer than that of a young person. This particularly applies to the pulmonary cases; many sufferers over 55 years of age today are rather unfairly classified as cases of chronic bronchitis and diverted to the chronic wards. The long-stay classification based on six months in hospital would bring many of these patients into the acute wards, where full examination should at any rate distinguish those with carcinoma of lung, or tuberculosis. Patients with cardiac conditions, particularly those with signs of cardiac failure, would more probably gravitate into the long-stay group.

The group of patients with senile dementia associated with cardiovascular changes would go either to a mental or to a long-stay unit, depending on their symptoms. Many elderly patients develop mental symptoms, and they present a serious problem. Their mental and physical hyperactivity makes them difficult to manage at home, and since it became so difficult to find them hospital beds, there has been a growing tendency to gain their admission by using an order under the Lunacy Acts. This seems unjust, for it often happens that the period of hyperexcitability precedes a calm, which heralds a fatal termination. It is true that hospital beds are often sought for elderly people who have developed ailments which could quite well be treated in the home: the usual plea is that there is no-one to look after the old man or woman at home. Many who manage to live quite well by themselves in a room are dependent on others when they fall sick: but they cannot indefinitely depend on the good will of a neighbour to feed and look after them, however small the amount of attention. In such circumstances the old person's condition tends to deteriorate and the requests are renewed to the hospital for admission. It is true that the service of home helps is designed to assist such persons, but often the home helps are only available on paper and not in a material form, and until there is a great change in our social and housing position this group of patients should—if only for reasons of humanity—be referred to the long-stay unit. The unit, with their team, should give domiciliary care working closely with the patient's own doctor. Only in this way can cases be selected fairly for admission to hospital; and in this way we could ensure that these people do not continue indefinitely unattended and without help.

Young Long-stay Sick.—The term "chronic sick" is often associated with the idea of old age; but the long-stay sick group unfortunately includes many young people. Among them are patients with nervous lesions such as disseminated sclerosis, rheumatic lesions (chiefly rheumatoid arthritis), certain cardiac and pulmonary lesions, and incurable cancer.

Transferred Cases from Acute Units.—A further group includes cases which other units have transferred as hopeless, and for which no treatment has any immediate prospect of success. Some come within the categories already defined, and have been passed on from acute wards or from special departments. Among them are skin cases and orthopædic cases. These patients should be carefully vetted before being readily accepted as long-stay cases. It may be necessary that a patient who is blocking an acute bed should be transferred as soon as possible, but the choice of patient to be moved should rest with more senior members of the acute away in the hand. The third hazard is of irritation by, or sensitisation to, the chemicals employed; probably this is not of much significance, for it is said that after thirty million cold waves had been given in the U.S.A. the number of allegations of dermatitis or damage to the hair or scalp was still very small. The fourth hazard—which appears to be only of theoretical importance—concerns toxic effects on the liver, kidneys, and hæmopoietic system.

Reports on the medical aspects of cold waving are meagre and conflicting. Goldman and his colleagues,[6] while they seem to believe that irritation and sensitisation may arise from the use of thioglycolate solutions, emphasise that if dermatitis comes on after a cold wave the following chemicals must be considered: the preliminary shampoo, the preliminary cleansing lotion (if used), the cold-wave material, the oxidising agent, and the post-treatment shampoo and wave-setting material (if these are employed). A more recent report by Behrman and others [7] states that of 390 members of a group who had varying contacts with cold-waving solutions, only 0·26% reacted to patch tests. Of 226 factory employees carefully investigated for evidence of toxic effects caused by the solutions concerned (72 being daily in close contact with the chemicals), none showed evidence of acute or chronic disease of the liver, kidneys, or hæmopoietic system which could be attributed to their work. Those who wish to pursue the matter further may refer to a recent review by MacKenna.[8]

The lesson that emerges from these studies is that when a patient alleges that dermatitis has been caused by cold-waving solutions, her explanation should not be accepted until other chemicals which have been applied to the hair and scalp are proved guiltless.

FOR PARENTS OF MENTAL DEFECTIVES

The discovery that a child is mentally defective often comes as a bitter blow to parents, and one which they find it hard to accept. All who have worked with mental defectives know those tragic parents who take the baby from doctor to doctor and scan the face of each for a reprieve. The only way to help these parents is to teach them to accept the child's defect and enjoy his other qualities. Nearly all mentally defective children are lovable, and once the criterion of intelligence is set aside they are often found to be the peers, or indeed the superiors, of their contemporaries in other qualities. They may be affectionate, obedient, easily pleased, and friendly to strangers, and they are usually lighthearted. The National Association of Mental Health have published a pamphlet [9] encouraging parents to accept the disability and help the child to make the most of the intelligence he has. They are warned that the task of teaching will be a slow one, and that much patience will be needed to get him to learn the movements which other children pick up unnoticed. A list is given of equipment useful in his training—such things as bean bags and bales to teach him to throw and catch; water and sand; a doll to dress and undress; push-and-pull toys; painted cotton reels to thread; and strips of cloth nailed to a board, carrying buttons and button-holes to do up, or laces to practise lacing his shoes and tying bows. An account in the appendix by an American mother of how she came to understand the position and to help and enjoy her child makes instructive as well as moving reading.

ANKYLOSING SPONDYLITIS

Though ankylosing spondylitis is commoner used to think, careful studies of large series are still rare enough to earn our gratitude. accounts have lately been published—one, on 1 by Mowbray and his colleagues [1] at Newcastle, other, on 73 cases, by Hart and others,[2] f Westminster Hospital. The two groups agree fundamental point—the absolute distinction ankylosing spondylitis and rheumatoid arthritis; is quoted of a miner who suffered simultane both conditions, which progressed independ at different rates. Both articles dwell on the bi distinctions between the two diseases. Serum-fl tests, whether of the thymol-turbidity or the coll variety, are rarely positive in spondylitis though so in rheumatoid cases; and the only point of r between the two disorders is the tendency to re the serum albumin-globulin ratio—which may that in both some infective factor is at work. been suggested that the preponderance of males sufferers from spondylitis implies an endocrine but careful estimation of urinary 17-ketosteroid gave essentially normal findings.

The Newcastle workers postulate an initial d osteoclastic stage, followed by a sclerotic ost reaction, while the Westminster group suggest least some of the apparent destructive sacro-iliac is really due to superimposition on the joint the X-ray film of patchy iliac sclerosis which is para-articular. Hart and his colleagues found that earliest symptom was lumbosacral backache, and three-quarters of the cases had sciatica at some or other, which arouses the suspicion that a diagnosis of disc prolapse is still being made in men who really have spondylitis. As regards trea strict rest or immobilisation of any kind is said cause deterioration and stiffness, and there is objection to physiotherapy except in the form of X-ray therapy is the treatment of choice, given not the original wide-field applications advocated by but to the spine alone and only to the known areas. But surely Hart and his associates are on firm ground in decrying the value of surgical assist especially since they also emphasise the fatal infl of hip involvement on the prognosis. The fact is bilateral hip-fusion demands an arthroplasty of kind, which makes all the difference to comfort capacity.

Finally, the Westminster Hospital report insists, ankylosing spondylitis can be diagnosed with ease than most conditions in medicine, and that chronic joint diseases affect earning capacity so This may be a rather optimistic estimate; but cert fewer bowed cripples would be seen in our streets their condition had been diagnosed before the sp changes became irreversible. In the Westminster Hos cases, the average interval between onset of sym and diagnosis was almost three years.

On Oct. 10 the King visited Sir Maurice C at his London home to invest him with the G.C.V The honour was conferred last May after the K illness, but injuries received in a car accident prevented Sir Maurice from going to Buckingham Palace

Dr. Geoffrey Marshall will deliver the Harveian oration to the Royal College of Physicians of London, Pall Mall East, S.W.1, on St. Luke's Day, Tuesday, Oct. 18, at 3 P.M. He is to speak on Individuality in Medicine.

YSICIAN-SUPERINTENDENT AND MEDICAL DIRECTOR,
BRIGHTON GENERAL HOSPITAL

term "chronic sick" is so vague and so difficult ine that some other would be better: and I would t that the whole range of this class of patient be d "long-stay" and not chronic. It is obvious those making up the total include many medical ories, some of which are set out below.

TUBERCULOSIS AND CANCER

es of Tuberculosis.—These are already tackled ately, and the combination of clinic, chest unit, orium, and mass-radiographic unit should produce esired result in due course. The question of infec- is receiving attention, and the early diagnosis and val of patients from the general population should n the incidence of further infection, besides offering est prospects of cure to the sufferer.

es of Malignant Disease.—Malignancy, the most d killer of mankind in the present age, also deserves e tackled as an individual problem. If infection was ature of the illness an effort would probably be made lar to that made for tuberculosis. Cancer is so spread that patients must be treated at the outset cute units; many go on to long-stay units, chiefly symptomatic treatment. Probably we need fairly e special units where concentrated and specialised tment can be given. It should be possible to select ients for admission to such units by answering the ple question "It it cancer or not?" Admission to h a specialised unit should be a boon and comfort to sufferer, for the public are already "cancer-minded," the mental state of a patient cannot be improved inactivity and bluff. It is far better, surely, to offer atment in a big way.

THE OTHER PATIENTS

With these two medical categories disposed of, what er groups of long-stay sick remain? Who shall care them, and where?

I suggest that the term long-stay patient should be plied to those who are not likely to be less than six onths in hospital. All patients who can possibly be red within six months, and also those who, within at time, can be sufficiently relieved for them to return normal and usual employment should go to acute its.

Senile Cases.—The physical age of human beings annot be defined entirely by the age in years. Many the 70–80 age-group are physically and mentally etter than some in the 65–70 age-group; and the easons must be sought by careful study of both indi-viduals and groups. By proper organisation of patients n this geriatric group the stage of physical and mental weakness with double incontinence may be avoided or delayed. Those who reach this penultimate stage can only receive nursing care, and should therefore be housed in long-stay annexes where this can be provided.

Elderly Long-stay Sick.—Various conditions can affect the elderly; this group will include people *over 55 years of age* suffering from all types of ailments, and whose recovery-rate is retarded. Apart from malignancy, which has already been mentioned, chest troubles probably claim the greatest number of victims, with cardiovascular diseases second.

The elderly are prone to the same diseases as the young, but their resistance is often diminished and their condition likely to be aggravated by repeated attacks of their "seasonal" trouble. Thus, at some stage, their illness is likely to become more protracted, and the time when they become classified as chronic sick is a matter of chance. Some acquire the label when they should really be eligible for treatment as acute cases, simply because it is known that their convalescence is likely to take longer than that of a young person. This particularly applies to the pulmonary cases; many sufferers over 55 years of age today are rather unfairly classified as cases of chronic bronchitis and diverted to the chronic wards. The long-stay classification based on six months in hospital would bring many of these patients into the acute wards, where full examination should at any rate distinguish those with carcinoma of lung, or tuberculosis. Patients with cardiac conditions, particularly those with signs of cardiac failure, would more probably gravitate into the long-stay group.

The group of patients with senile dementia associated with cardiovascular changes would go either to a mental or to a long-stay unit, depending on their symptoms. Many elderly patients develop mental symptoms, and they present a serious problem. Their mental and physical hyperactivity makes them difficult to manage at home, and since it became so difficult to find them hospital beds, there has been a growing tendency to gain their admission by using an order under the Lunacy Acts. This seems unjust, for it often happens that the period of hyperexcitability precedes a calm, which heralds a fatal termination. It is true that hospital beds are often sought for elderly people who have developed ailments which could quite well be treated in the home: the usual plea is that there is no-one to look after the old man or woman at home. Many who manage to live quite well by themselves in a room are dependent on others when they fall sick; but they cannot indefinitely depend on the good will of a neighbour to feed and look after them, however small the amount of attention. In such circumstances the old person's condition tends to deteriorate and the requests are renewed to the hospital for admission. It is true that the service of home helps is designed to assist such persons, but often the home helps are only available on paper and not in a material form, and until there is a great change in our social and housing position this group of patients should—if only for reasons of humanity—be referred to the long-stay unit. The unit, with their team, should give domiciliary care working closely with the patient's own doctor. Only in this way can cases be selected fairly for admission to hospital: and in this way we could ensure that these people do not continue indefinitely unattended and without help.

Young Long-stay Sick.—The term "chronic sick" is often associated with the idea of old age; but the long-stay sick group unfortunately includes many young people. Among them are patients with nervous lesions such as disseminated sclerosis, rheumatic lesions (chiefly rheumatoid arthritis), certain cardiac and pulmonary lesions, and incurable cancer.

Transferred Cases from Acute Units.—A further group includes cases which other units have transferred as hopeless, and for which no treatment has any immediate prospect of success. Some come within the categories already defined, and have been passed on from acute wards or from special departments. Among them are skin cases and orthopædic cases. These patients should be carefully vetted before being readily accepted as long-stay cases. It may be necessary that a patient who is blocking an acute bed should be transferred as soon as possible, but the choice of patient to be moved should rest with more senior members of the acute hospital medical staff than has been customary in the past.

STAFFING

The long-stay unit staff must be a carefully selected team of medical, nursing, and ancillary personnel. The patience and continuous effort needed in the care of this class of patient cannot be expected from every member of the nursing and ancillary professions. The ancillary team must include physiotherapists, social and domiciliary workers, and dietitians. The long-stay unit must be recognised as an important *nursing* unit. It should maintain a strong link with acute and special units, and all nurses in training should have a period in the main ward and annexes of the long-stay unit. The main long-stay unit would thus become an important part of the complete training-school, whether a single hospital or in a group.

An exception might be made for wards occupied by the physically and mentally weak, most of whom are doubly incontinent. Prospects of improvement in our hospitals are at present somewhat remote, and the best should therefore be made of accommodation now available. The chief requirement of these patients is good nursing care, and it might be well to leave their wards outside the training-school and place them under independent trained staff supplemented by assistant nurses, nursing orderlies, and ward orderlies. The care of such patients is regarded as unattractive by nurses in training; and those choosing permanent employment in this work are likely to be looked down on. Many of the men and women who undertake it lack the education nowadays required in order to pass nursing examinations; but it has been my experience that they are often first-class practical nurses—not the mere domestics of the nursing profession, but people who take a pride in their work and deserve more praise and higher status than they have at present. They need encouragement in the unpleasant job of work they are doing, and I think it would be easier to enhance and encourage their work if they were set apart from the influence of the matron and senior nursing staff of a training-school. Let this section be put under a trained nursing head, who, supported by certificated nurses and non-trained staff, would have a personal and full-time interest in managing it.

ACCOMMODATION

The long-stay unit team have not the happy prospect of seeing their patients make a quick recovery; and patients transferred from the acute wards to the long-stay unit realise that their hopes of a quick recovery are less than when they first entered hospital. Their depression should be minimised; and I advise that the main long-stay unit, which would act as the filter for a long-stay annexe, should be the brightest and most convenient that can be obtained. Ground-floor wards have much in their favour, since patients can be wheeled out into the fresh air and sunshine; and gardens made colourful with flowers do much to uplift the morale of sick people. The staff selected for work with long-stay patients find the work more attractive if they do it in good bright cheerful surroundings.

To allow long-stay patients to be "dumped" in dull dreary old institutional wards frustrates the efforts of those working for them. Such a tragic and pitiful error, if it were perpetuated, might well bring recriminations on the health service as a whole.

THE FIRST YEAR

REVIEW BY THE MINISTER

OVER two hundred press representatives last heard Mr. Aneurin Bevan, the Minister of the first year of the National Health Service in and Wales.

Mr. Bevan claimed that the transition from system to the new had been accomplished very Most of the shortcomings of the scheme were to intrinsic defects, but to the overwhelming need that had been disclosed. The cost of the was about £300 million a year—twice the sum estimated, the increase being attributable increases in remuneration. There was no knowing what citizens used to spend on medical One estimate was £250 million per annum, though himself believed that the total was still larger.

The cost of the new service would be greater but the voluntary work of the 12,000 people administered it through the various statutory bo Thanks to them, administrative expenses were 2·5–3% of the total. Little further saving could expected here; administration was already "stre lined."

Abuse of the service there certainly had been; the prominence given to reports of abuse had given false impression of its prevalence. One reason why patient might abuse the service was the desire to " my money's worth" for the weekly contributions; this desire sprang from misapprehension of the purpo served by the National Insurance contributions. (point of fact, the health service benefited from the contributions only to the extent of some £40 millio per annum.) By those operating the service, abuse ha been rare; hitherto the central tribunal had heard fi appeals against disciplinary action.

Mr. Bevan pleaded for economy in prescribing. Th average cost per prescription was 2*s.* 9*d.* Over-prescribin was commonest in respect, not of expensive drugs, bu of everyday medicaments such as aspirin and cotton wool; and he asked that the general practitioner should be prudent and that the patient should not be importunate. A committee, headed by Sir Henry Cohen, wa drawing up a list of drugs that could be provided by general practitioners. "Sometimes general practitioners prescribe certain drugs which are far more expensive than other drugs which are quite as suitable."

In answer to a question, the Minister admitted that he had no figures to show how much time the practitioner now spent on paper-work. "I have also not got any analysis of the time it took a general practitioner to fill up his bills before."

On health centres he declared his intention "to go steadily but cautiously." These centres must take their place in the queue; in the capital-investment programme other items came first.

The rush for spectacles was far greater than had been anticipated. Over 5 million pairs had been supplied, and a further 3 million were on order. Now, however, spectacles were being produced at the rate of 7 million pairs a year; and production would be equal to the current demand by the end of this year. As to hearing-aids, 29,000 had been issued, and it was hoped that the total would be up to 150,000 by the end of next year. The delay was not in manufacture but in dispensing.

Questioned about possible economies, Mr. Bevan said that these might be possible on the supplies side, through standardisation and central ordering. For example, the Government hearing-aid, which was better than some for which people paid £40–50, was being produced for a little over £4.

Asked about the cost to the nation of visitors from overseas who receive free medical attention in this

---

"... In order to become good or adequate members of a community it is necessary for us to observe certain standards of decency and coöperation, and to observe them *all the time.* ... But what we wanted to do as infants (and what it is in our nature to want to do today) is to be very generous and friendly and coöperative at one moment, and very selfish and aggressive at another—very decent one minute and very indecent the next."—Dr. RANYARD WEST, *Psychology and World Order*, London, 1945.

y, Mr. Bevan said: "This story about lascars g over, getting artificial teeth, and selling them l is an example of journalistic imagination." e was allowed to enter the country simply to t by the service. On the basis of a month's stay, the service in the same way as did British citizens, al attention to 633,000 foreign visitors (last year's would cost the country about £200,000 a year. He opeful that reciprocal arrangements between this ther countries might be completed; the parties to russels Pact were being approached.

Bevan was closely questioned about a possible tax for medical service. "If by that," he said, neant a payment by the patient at the moment the patient needs treatment, then we have set our against it." Asked about payment for medicines, eclared: "It would require an alteration of the te to do it and the difficulty here is that if the nt to be paid by a patient is to be a deterrent, it be more than nominal. If it is more than nominal y be a hardship in some cases." To a suggestion a payment of 10s. should be made for spectacles, he ted that this would tell hard on the old-age pen- r. Asked whether the weekly contribution might creased, he replied: "The possibilities of taxation nfinite."

e Minister's review included the following further es:

NCTIONS AND STAFFING OF HOSPITALS

The following important statement has been received by gional hospital boards from the Ministry of Health.

Under the National Health Service (Functions of gional Hospital Boards, &c.) Regulations (S.I., 1948, o. 60) the Minister's powers for planning and developing e hospital and specialist services were, subject to rection, delegated to regional hospital boards and oards of governors. It is therefore competent to the oard, subject to direction, to make changes in the use f hospitals without prior reference to the Minister. The inister is aware that boards have been considering hanges of user in the hospitals under their administration, and it is right and proper that they should do so.

The Minister is anxious to avoid intervening where oards have arrived at a decision after full consideration, ut the delegation of powers is subject to direction on is part, and under section 6 (4) of the Act he is bound n using hospitals transferred to him by the Act "so far as practicable" to "secure that the objects for which [they were] used immediately before the appointed day are not prejudiced by the provisions of this section" (i.e., transfer to the Minister). He cannot, therefore, ignore representations made to him by members of the public and the profession, and may feel bound at any time to call upon a board to report to him their reasons for adopting their new policy. It is undesirable for this to happen after the actual process of change has been begun, and he thinks boards will find it useful, where a proposal is likely to give rise to substantial local or professional opposition, to keep the Department informed of their plans at all stages.

Boards may find useful the following indication of the Minister's views on a number of matters that arise in connexion with changes of use of hospitals. The principal factors are, of course (1) the possible loss of service to patients, and (2) the disturbance of medical staff.

Change from one specialty to another or from a general to a special hospital.—In the case of infectious-disease and smallpox hospitals, which tend to be redundant owing to centralisation, little difficulty is expected provided that regional boards have assured themselves that the new centralised facilities meet anticipated needs and have done their best to secure that the staffs of the redundant hospitals are not prejudiced by the change. In the case of other changes of this nature—i.e., from one special use to another or from general to special hospital—the difficulties encountered may be more serious; in particular, where a hospital of long-standing repute is concerned, the board should see that the medical staff of the hospital has free opportunity of having its views considered by the board or their planning committee orally if possible. An open meeting at which the proposal can be explained and members of the public can express their views may sometimes be desirable, particularly where it is proposed to use a small local general hospital for other purposes, since the local loyalty that such hospitals command must not be ignored even where reorganisation is expected to produce greater medical efficiency.

Change from general-practitioner (cottage) hospital to specialist hospital.—Local loyalty is again a factor of great importance. In the past general-practitioner hospitals have, owing to the uneven distribution of consultants, been compelled at times to undertake work for which they were not properly equipped, and they have often been criticised for trying to do too much. The introduction of the National Health Service, and in particular the present review of establishments, has given an opportunity for improving this state of affairs and for developing hospitals staffed by consultants even in smaller centres. The Minister is wholeheartedly in favour of development in this direction but would ask regional hospital boards to make sure that in carrying out their plans they are not depriving local patients of a valuable feature of the general-practitioner (cottage) hospital—i.e., its use as a local hospital to which the general practitioners of the neighbourhood can admit patients who require treatment within the scope of a general practitioner but who, for various good reasons, cannot be treated at home. It is, in the Minister's view, very valuable for the general-practitioner service of the district when the family doctor has access to beds where patients of this type can be in his charge and he knows he can readily call upon the services of a consultant for a second opinion, and it is essential if the level of general-practitioner medicine is to be maintained that the interchange of ideas between general practitioners and specialists should be facilitated by such consultation and by informal contacts on the occasion of regular visits from consultants to general-practitioner hospitals. If such arrangements can be supplemented by the offer of a number of "clinical assistantships" to general practitioners as part of a team in the district general hospital so much the better, but in the Minister's view the latter is not a substitute for the former, and if the result of reorganisation is to deprive general practitioners of charge of hospital beds something valuable has been lost. In particular the Minister wishes regional boards to guard against the feeling that local cottage hospitals are merely buildings to be used as additional accommodation for relieving pressure on beds at the district general hospital of the group. There may be cases where it will improve the efficiency of the group organisation for a general-practitioner hospital within that group to be used as a specialist department—e.g., as a maternity unit, recovery hospital, or geriatric unit. But if the loss to the district of the "general-practitioner beds" is to be avoided the board should make arrangements for the general practitioners of the district to have charge of a number of beds in the district hospital or elsewhere which can then serve, in the way described above, as a "general-practitioner wing."

General-practitioner maternity hospitals.—It has been the general practice to have obstetricians in charge of maternity departments and maternity hospitals. While recognising the merits of this policy in the large unit where teaching and training is undertaken, the Minister feels that he should remind boards that in the smaller types of maternity unit booking normal cases, staffing must necessarily vary. Where, in the larger of these, selected general-practitioner obstetricians have been in charge in the past, boards should carefully consider the position before altering the nature of the services provided and should be cautious about depriving general-practitioner obstetricians of the charge of maternity beds. In the smaller cottage-hospital type of provision where general practitioners attend their own patients a selected general-practitioner obstetrician should have the general oversight of the unit. Boards should endeavour to link the smaller units with the nearest maternity department and make readily available to the general-practitioner obstetricians concerned the consultant obstetric services of the larger hospital.

NARCOTIC POISONING

It is announced in the *Journal* of the Danish Medical Association[1] that from now onwards, all the cases of narcotic poisoning in Copenhagen requiring hospital treatment are to be drafted into the same hospital. Certain of Copenhagen's hospitals having been invited to undertake this task and having declined it, the psychiatric department of the Bispebjerg Hospital gave its consent to a scheme in which the doctors of Copenhagen and its ambulance services are henceforth to participate. The rule is that any unconscious patients, for whose condition no other reason than narcotic poisoning is forthcoming, are to be conveyed to the Bispebjerg Hospital whatever the regulations hitherto in vogue. As long as they are unconscious, these patients are kept in the psychiatric department. On the return of consciousness they are drafted to another section of this department if psychiatric after-treatment is desirable. Otherwise they may be transferred to a "somatic" section of the hospital. This innovation is regarded as the logical outcome of the revolution which has taken place in the treatment of narcotic poisoning: as matters now stand, many hospitals cannot provide the technically skilled staff nor the costly apparatus required for the up-to-date treatment of these patients whose fate so often hangs most delicately in the balance.

One of the Danish pioneers in this field is Dr. Aage Kirkegaard, who has described[2] the advances made of late years. As he points out the unconscious patient suffering from barbiturate poisoning needs the closest supervision, with a record of the respiration, pulse, temperature, blood-pressure, and percentage of hæmoglobin every four hours, not to mention daily plasma analyses. To avoid aspiration into the lungs, all irrigation of the stomach should be carried out in the Trendelenburg position, and the threat of acute œdema of the lungs must at once be met by the administration of glucose or sucrose, supplemented if need be by strophanthin, or oxygen, with or without carbon dioxide, to combat the danger of collapse. Analeptics of the leptazol group, the sulphonamides (for the prevention of pneumonia), blood-transfusion (for the prevention of secondary shock), and gastric irrigation with charcoal and magnesium sulphate are only some of the many modern weapons against narcotic poisoning.

In England Now

A Running Commentary by Peripatetic Co[illegible]

OUR firstborn is a holy terror. From 6.30 P.M. to [illegible] he is quiet, recuperating his forces. For the rest [illegible] day he rarely requires less than one adult's [illegible] attention to keep himself, the garden, and the [illegible] destruction. He crawls on his bottom by a [illegible] his own; his speed is great and his reach [illegible] He collects and eats with equal gusto handfuls of green tomatoes, weeds from the compost-heap, and windfall apples. Indoors he tears off wallpaper, [illegible] the cat's milk, blacks himself at the stove, falls [illegible] stairs, or "reads" several shelves of books at once, with the same disarming enjoyment and relen[illegible] industry.

It leads me to remember with envy two children I [illegible] a year or so ago on staff round. Two quiet, bidd[illegible] children who sat with smiling inattention side by [illegible] while their physician (he has since, poor man, gon[illegible] be professor at St. Ethelred's) discoursed about the [illegible] doctors who had forgotten to raise the dose of thy[illegible] as they grew. They were, of course, mild cretins. [illegible] only *our* incubus was a mild cretin! And why [illegible] A little daily dose of thiouracil, and we too would [illegible] a quiet, biddable child. Or so it seems. We have [illegible] yet tried it, but if we are to have a garden at all [illegible] year we may be driven to it.

Thiouracil as a poison seems to have been surprisi[illegible] neglected. How much more subtle a means than ars[illegible] to silence a too suspicious or too talkative w[illegible] "Administering a drug with unlawful intent" perhaps, something of the sort, but they could hardly call [illegible] murder.

Dorothy Sayers (I think it was) had the opposite [illegible] once—of a villain who kept the cretin heroine in sub[illegible]tion by stopping her thyroxine. It is a pity that like so[illegible] others of Miss Sayers's medica[illegible] (remem[illegible] the fatal air embolism produced [illegible] it has its flaws. No cretin, least of all one [illegible] irregularly as this lady was, has apparently m[illegible] prospect of growing up to look like a really truly hero[illegible] A thought this to stay our hand [illegible] our own infant. If we make him a [illegible] no-one will ever marry him, and then we shall never [illegible] our revenge watching him try to deal with his own brat in his turn.

* * *

It is paradoxical that in the heart of London [illegible] should be difficult to sleep at night for the noise of the birds; but that is just what has happened now the hordes of alien starlings have descended on us once more for the winter. A little before sunset they darken the sky over Westminster Bridge as they dash madly round in ever-changing cohorts and swoop on to the County Hall, where they occupy every ridge and rail of the roof and chimney-stacks. Later they take up their quarters for the night in the plane-trees outside St. Thomas's Hospital. It would not be so bad if only they slept throughout the night, but every half-hour or so, disturbed by a tram, a late reveller, or the milkman collecting (and rattling) empty milk-bottles, the starlings panic, chattering and whistling (who on earth called it a murmuration?) loudly enough to waken the sleepers, or rather to keep all would-be sleepers from sleep. And what a filthy mess they make on the pavements!

* * *

I do wish that barbed wire were not so plentiful; indeed I think I should go so far as to forbid its use. The lovely fields where once I used to walk are bristling with it, and I particularly regret that a little wood where one could gather primroses in the spring is now fenced with six rows of barbed wire. No livestock is kept in the wood and the barbed wire seems to be a gesture of defiance to those who love primroses. It seems to be a matter for the Council for the Preservation of Rural England.

Apart from this minor irritation, the Sedgemoor lanes are lovelier than ever. John and I tried to find the battlefield; but we were unsuccessful, even with the directions given by the Vicar of Weston Zoyland, who

Letters to the Editor

CONTROL OF TUBERCULOSIS

SIR,—The hurricane is now blowing up over the reorganisation of the tuberculosis services; witness the sequelæ of Mr. Francis's article (*Lancet*, Sept. 24) in the *Times* and the recent speech of Sir Andrew Davidson.

What have we gained by the transfer from local authority to regional board? Firstly, the recognition that the tuberculous patient deserves a high level of skill in diagnosis and treatment, and that this can best be achieved by offering to the responsible physicians the possibility of a status and mode of work exactly comparable to that in other specialties: the efficient chest physician will, as the result of his clinical work, directly reduce wastage of his patient's life, and indirectly wastage of the lives of the patient's contacts. Secondly, we have gained the advantages of the planning and pooling of resources at regional level and the escape from the stagnant pool of some backward local authorities.

Much is now heard about the temptation for the chest physician to neglect the preventive aspects. I wonder if this is really valid. Many of my generation who were unattracted by what wrongly seemed to us the rather sterile duties of the medical officer of health, gladly became disciples of that wider aspect of prevention which has been attractively presented by Professor Ryle. A minority may have entered the tuberculosis services because they were unfitted alike for consultant work and for the hurly-burly of general practice, but presumably the great majority of permanent tuberculosis officers and chest physicians were, and are, clinicians with a natural vocation for what is now called social medicine.

Our work does not divide itself into two separate divisions; but we organise ourselves and our clerical staff so that justice is done to all aspects. It therefore makes no sense to be told that we must set aside x hours to coöperate with the medical officer of health; if the attitude is right, the coöperation is continuous and real, and time spent on pure "administration" is negligible.

It will be a retrograde step if the authorities decide that chest physicians are to be in direct contract with both regional boards and local authorities; we understand perfectly well the need for the closest liaison. A servant justly treated will happily serve one master and perform that master's wishes; he would resent his master arbitrarily paying him on two different scales for what is essentially all the same service. If a second master paid him on another scale, he would be mindful of the Biblical injunction.

On the preventive and environmental side we gladly do all we can, but the main factors are outside our control. We remain baffled by the administrative divorcement of health and housing at local-authority level.

Cheltenham. F. KNIGHTS.

SIR,—In his article of Sept. 24 Mr. Francis concludes that "data collected in a table indicate that B.C.G. may cause a fivefold reduction in the morbidity and mortality of tuberculosis." This (and other) evidence make unnecessary. he suggests, a "statistically satisfactory trial" in this country.

Being unfamiliar with one set of the data included in this table, I thought it wise to study it in the original.[1] This is what I found. The trial took place amongst Indian infants in Saskatchewan and the author's description of it is as follows:

> "B.C.G. vaccination of Indian infants was begun in 1933. All Indian infants born in the Qu'Appelle Indian Health

---

[1] Ferguson R. G., Simes, A. B. *Tubercle*, 1949, 30, 5.

> Unit during the period October, 1933, to December, 1945, were considered for study. Follow-up information up to August, 1947, was studied. Families of comparable status in respect of housing, sanitation and certain other economic and social factors likely to affect the health of children were paired, and one member of each such pair was allotted at random to one of two groups, designated 'Group A' and 'Group B.' All children born into the families of *Group A were vaccinated in one year, while all children* born into families of Group B in the same year were taken as controls. In the following year this situation would be reversed and so on throughout the duration of the study. This procedure resulted over a period of years in groups of 306 vaccinated and 303 unvaccinated, which were balanced in respect of both age and environmental factors considered. . . . Infants were vaccinated within ten days of birth. . . . Both vaccinated and control children lived in a reservation environment where the infection rate was 68·7 per cent. at an average age of 9 years."

Amongst the 306 vaccinated infants there were 6 cases of tuberculosis with 2 deaths; amongst the 303 control infants 29 cases and 9 deaths—i.e., Mr. Francis's fivefold reduction. This is clearly an important difference, and Mr. Francis informs us that "every precaution appears to have been taken to make the groups comparable." Yet taking the authors' table IV it seems to me that the *infants in the trial must have been observed for the* following lengths of time:

Time observed, years	*Controls*	*Vaccinated*
Less than 1	42	15
1–2	23	18
2–3	27	13
3–4	20	18
4–5	27	29
5–6	23	21
6–7	24	11
7–8	13	23
8–9	21	15
9–10	21	18
10–11	9	27
11–12	16	21
12–13	2	39
13–14	21	2
14–15	14	0
	303	306

These figures appear very odd in more respects than one. As the first infants to be included were born in October, 1933, how can 14 controls have possibly been followed for 14–15 years by August, 1947? Far more disturbing still are the *gross* differences between the vaccinated and control children. Why, with the careful method of allocation laid down, should 35 control infants and only 2 vaccinated come into the groups watched for 13–15 years? Why, reversing the situation, should there be 39 vaccinated against 2 controls watched for 12–13 years? *And large differences may also be seen at other* points on the time-scale. Can such figures give the equality of age, &c., that is claimed both by the authors and Mr. Francis? Turning secondly to the environment, Ferguson and Simes give the following figures in their table III for the infection-rate year by year based on remainders:

Year	*Number remaining negative*	*Number turning positive*
1	157	10
2	147	10
3	137	6
4	131	16
5	115	7
6	108	11
7	97	10
8	87	7
9	80	7
10	73	6
11	67	3
12–15	64	15
		108

These figures are said to reveal "the infection rate among the controls using only those controls that had adequate tuberculin information." We may waive the point (to which incidentally no attention is paid) whether these cases are a representative sample of all the controls. For the main issue is, how do the authors come at all by 157 controls observed year by year for 15 years? There *is* no such group in their control data—indeed only 37 have been followed for more than 12 years. And why, on the basis of these figures, do they conclude that the "infection rate" was 68·7% (i.e., 108/157) "at an average age of 9 years"? The table quoted above clearly sets out a population for 15 years.

These are not statistical quibblings about ine
That the two groups to be compared are alike ex
the respect of B.C.G. vaccination is fundamental.
we should have accurate figures of the environm
desirable. Perhaps these two groups were
perhaps there are simple explanations of the discrep
to which I refer. But until we have those explana
the figures can command no confidence; the cri
reader must inevitably and wholly reject the cl
made for them.

I am not concerned here, I would stress, with
general body *of evidence in favour of (or against)*
I am concerned only that a particular piece of "evide
—and others like it—should not continually be ca
the face of those who think there is still in this cou
a case for the "statistically satisfactory trial"
Mr. Francis categorically rejects. And the fact that
evidence in favour of some other inoculation proce
is weak seems to me to be no adequate reason for ad
yet another to the list without measuring its potential

A. BRADFORD HI

SIR,—In his inspired article of Sept. 24, Mr. Fra
invoked medicine for an all-out offensive on tubercu
—a preventable disease.

A subsequent leading article and correspondence
the *Times* suggested that the chest physician and med
officer of health were not sufficiently active in
preventive field. The main preventive requireme
protection of the healthy from infection, and whilst
nation's nutrition remains sufficient, adequate hou
is a number-one health priority whose absence is
stumbling-block to all other *anti-tuberculosis* measu

The value of mass radiography is limited if infecti
cases cannot be adequately isolated. B.C.G. vaccinat
is reduced in value if, at the time of vaccination, the inf
is infected with virulent bacteria from another member
the household.

The chest physician and medical officer of health
continually uniting to obtain the bare necessities
housing conditions, but even in the case of kno
dangerously infectious households relief can only occ
sionally be obtained. For every known infectious c
there are many unknown. Inadequate housing of th
majority of the population—urban and rural—is probab
the *root* cause of many other diseases, organic a
functional.

In highly susceptible herds in some countries, tube
culosis has been eradicated by isolating infected a
infectious animals and providing a high standard
living-quarters for attested herds. In this country th
standard of living-quarters for attested herds has to b
maintained at a high level.

The living accommodation for the majority of th
people is inadequate *and does* not improve. Truly w
can learn from experience with animals. Homes for a
and no deterioration in the standard of nutrition mus
be more than an election promise if tuberculosis is t
be prevented.

Newent, Glos.

HOSPITAL POSTS FOR THE MIDDLE-AGED

SIR,—May I support the plea by "Psychiatrist"
in your issue of Sept. 17? As one who was not "taken
over" on the appointed day by the relevant hospital
board, I can testify that private practice is disappearing,
with consequent financial embarrassment.

A host of authoritative articles and letters have been
published in the leading professional journals, advocating
action in favour of the downgraded or "misgraded"
specialists, but no-one has yet drawn attention to the
plight of an appreciable group of middle-aged specialists
and consultants who for some reason or other are

d from the hospital services. To say the least. efensible to keep highly skilled men from working. the same time to complain about the long waiting- r admission and delays in outpatient appoint- ; it should surely be possible to increase the r of outpatient sessions. *Quousque tandem?*

SPECIALIST.

FORTITUDE OF A FŒTUS

—In some women surprisingly little trauma is l to precipitate an abortion. Operations on the inal organs have a bad reputation in this respect. eration for appendicitis is followed by abortion or ture labour in 40–80% of cases.[1] In the following wo operations were done for acute abdominal ions during pregnancy in a woman with a bad ric history. Though at one time abortion ened, the patient was eventually delivered of baby.

X, aged 29, was first seen on Nov. 16, 1947, when she dmitted to the Liverpool Royal Infirmary with an lix abscess. The only previous illness which she ed was trinitrotoluene poisoning in 1942. Her obstetric was that in 1939 she had given birth at term to a hich was stillborn and macerated for no known reason. 1946 she had been delivered of a stillborn baby at fter having had pre-eclampsia during that pregnancy. pendix abscess was treated conservatively, and after ys in hospital the patient was discharged with the to return in three months for an appendicectomy.

n the patient did return on April 7, 1948, she was about weeks' pregnant, her last menstrual period having l on Jan. 6, 1948. There were no symptoms or signs endix trouble. In view of the unfortunate obstetric it was decided, after discussion, to postpone appendi- y until after delivery. However, six weeks later the t was readmitted, with recurrence of her appendix s, and was again treated conservatively. At that time radiography of the abdomen revealed numerous bismuth on tracks in the buttocks, and further questioning d the fact that the patient had received an incomplete of treatment for secondary syphilis in 1945.

this occasion there was no response to conservative res, and therefore on June 1 a large retrocæcal appendix s was drained, under general anæsthesia, by Mr. Maurice tone. At operation there was some soiling of the eal cavity. The postoperative course was stormy. ay after operation the patient threatened to abort, ortly afterwards she developed paralytic ileus. These cations were treated with morphine, gastric aspiration, travenous fluids. Progesterone was not given. After days peristalsis re-started and the patient's general ion steadily improved. The following week fœtal nents were felt for the first time. Sulphonamides and llin (16,400,000 units in 24 days) were given in the post- ive period. The discharge from the abscess ceased after eeks, and the patient was transferred to a convalescent

The pregnancy was then progressing normally. The Wassermann reaction was negative, but it was intended er the patient to a venereologist on her return from the lescent home.

July 18, however, she was readmitted, as an emergency with acute obstruction of small bowel. The uterus ponded in size to a 26-week pregnancy, and fœtal move- s were felt. It was thought that the cause of the obstruc- as a kink in the terminal ileum, which had been produced e enlarging uterus and adhesions in the right iliac fossa. w of the possibility that re-exploration of the appendix night light up a latent infection or precipitate abortion sturbing the uterus it was decided to do a short-circuiting tion. Accordingly on July 20 a side-to-side anastomosis en the terminal ileum and the transverse colon was done general anæsthesia, by Mr. Silverstone. Except for œa, which persisted for a week, the postoperative course neventful, and the patient was discharged from hospital ug. 1.

anwhile the pregnancy proceeded uneventfully, except ild hydramnios. On the advice of the venereologist, Dr. A. O. F. Ross, the patient was given penicillin 4,200,000 units in ten days. This was to be followed by 'Stabilarsan' 0·45 g. weekly until the end of the pregnancy, but only two injections of arsenic were in fact given.

She was admitted to the maternity ward on Oct. 1 in premature labour. She was very apprehensive—not unnaturally, in view of her previous obstetric history—and her apprehension was reflected in the incoördinate uterine action which marked her labour. The baby was eventually extracted with forceps, face to pubes, under local anæsthesia, the indications being secondary uterine inertia and small but persistent intrapartum hæmorrhage. At the end of the second stage intravenous ergometrine 0·5 mg. was given, and the placenta was delivered with the next contraction. However, a true atonic postpartum hæmorrhage followed, and a pint of matched blood was transfused. The intrapartum hæmorrhage, together with the postpartum loss, were most probably due to a lateral placenta prævia, but it was impossible to prove this.

The baby, a male, weighed 5 lb. 2 oz. and was judged to be of 38 weeks' maturity. He had asphyxia pallida at birth but responded to treatment, and when seen three months later had made satisfactory progress.

To summarise, this woman became pregnant after having had syphilis (incompletely treated), pre-eclampsia, and two stillbirths. After drainage of an appendix abscess she developed paralytic ileus and threatened to abort, and finally she underwent an operation for the relief of acute small-bowel obstruction, all within a span of 8 weeks. The child survived, during labour, an intrapartum hæmorrhage and secondary uterine inertia and, immediately after birth, asphyxia pallida.

We wish to thank Prof. C. A. Wells, Mr. M. Silverstone, and Prof. T. N. A. Jeffcoate, under whose care the patient was, for permission to publish this case.

CONCENTRATION OF DIPHTHERIA ANTITOXIN IN CORD BLOOD

SIR,—I cannot let Dr. Wiener's latest letter, which appeared last week, pass without comment.

I am glad that he has withdrawn his suggestion that the differences in antitoxic titre recorded between cord and maternal blood are too small to be significant; but he now suggests that the results might be affected by bias in the setting up of the experiment. A little consideration of the details given in my last letter should have shown him that this was highly improbable. We also have long series of thousands of records which show that the variation from guineapig to guineapig is not significantly greater than the variation between identical tests on the same guineapig. It is abundantly clear that Dr. Wiener is basing his criticism on his own experience of the much less accurate type of serological test with which he is familiar.

As regards our titrations, in the first place the cord and maternal samples were received at the same time and were therefore tested in parallel on one day using one animal, and the tests were repeated likewise. However, since there is no significant animal variation and the test toxin is always controlled by means of two standard sera, this particular "precaution" would be quite unnecessary. Nevertheless I accept Dr. Wiener's challenge by making available to him the protocols of the last set of tests made on mother's and cord blood samples:

Date, Sept.	*Guineapig*	*Antitoxin (units per ml.)* *Mother's blood*	*Antitoxin (units per ml.)* *Cord blood*
23	Same	18–22	36
24	Another	18–22	36–45
27	Another	20–22	>40
28	Another	..	40; <45

An earlier sample of the mother's blood, taken seven days before delivery, had the same value as this sample which was taken during labour. On the same four days tests on the two standard sera tested at 10% differences gave the following results: (*a*) 95, 95, 95, 88 units per ml.; (*b*) 2·07, 1·90, 2·10, 1·93 units per ml.

---

[1] r, J. L., Reis, R. A., Arens, R. A. *J. Amer. med. Ass.* 1932, 8, 1359.

Thus we found in this series of three tests that the mother's serum failed each time to pass tests for 22 units but was over 18 or 20 units, whereas the serum from the cord blood was over 36 units on each of the four occasions it was tested. The values allotted were 21 and 41 units respectively, and the high titres were due to the fact that the mother had been immunised earlier in pregnancy.

In conclusion I would suggest a better idea than Dr. Wiener's as to the relation between theory and observation: when an observation of undoubted accuracy conflicts with "an excellent theory," it is also a good thing to re-examine the theory. As yet we have no theory to account for the phenomenon, but we are continuing the investigation—giving due consideration to any points on the practical side which might throw light on the matter.

VASCULAR STASIS

SIR,—I read with great interest last week's letter on vascular stasis by Professor Kreyberg, of Oslo, and your annotation; and I should like to support the plea for further study of this phenomenon.

At this unit an investigation of experimental and clinical burns is in progress, and we have found evidence that the inflammatory reaction plays an important part in influencing the course of burns.

During a recent study[1] of experimental burns of known temperature applied for known periods in guineapigs, the permeability and qualitative blood-flow changes in the skin were investigated by the use of circulating Evans blue and/or brilliant vital-red injected before and after burning. It was shown: (1) that continuation of the dermal blood-flow in burned skin was accompanied by normal skin sensation, by the absence of marked œdema, and by the absence of subsequent whole-skin loss; (2) that the development of stasis of the local blood-flow in the dermis was preceded by marked œdema, was associated with analgesia, and was followed by whole-skin loss.

Further, evidence has been provided of the existence of a threshold dermal temperature, below which stasis does not occur. If, however, the dermis is heated to or beyond this temperature during burning, stasis of the dermal vessels develops. The time of onset of stasis decreases with increasing severity of burning. Stasis is preceded by a period during which slowing of the blood-flow progresses to extreme retardation or stagnation (prestasis of Kreyberg). During this period the vessels are freely permeable and œdema develops.

In our experience, stasis throughout the depth of the dermis in guineapig burns is invariably followed by whole-skin loss, and this would suggest that the change is normally irreversible. However, in a number of burns in which stagnation of the blood-flow was detected, partial, and not whole-skin, loss took place. This suggests that stagnation was not followed by stasis, or that if stasis did develop it was localised to the superficial part of the dermis.

Investigations are in progress with the aim of discovering how to influence these vascular changes. Various anti-histamine drugs have failed to influence the capillary-permeability and blood-flow changes in experimental guineapig burns of all degrees.[2]

In my opinion—and no doubt Dr. Kreyberg will [illegible] and stasis, when they occur, are part [illegible] y reaction, and any investigation into their nature and cause must take the whole into account.

Finally, I should like to comment on Kreyberg's choice of the word "prestasis" for retardation of the blood-flow. This word imp the condition invariably ends in stasis, Professor Kreyberg agrees that this is not true. In my opinion the word "stagnation" is from this criticism and is therefore to be preferred.

AN EPIDEMIC OF ACUTE NEPHRITIS

SIR,—I read with great interest Dr. Fleming's in your issue of May 7.

As physician in charge of the outpatient clinic of Transjordanian Red Crescent Society in Amman, I the same problem of an epidemic of acute nephritis infants of the Palestine Arab refugees.

In my private clinic in Amman, I have during the thirty months seen only three cases of acute neph But in the seven months between October, 1948, April, 1949, I saw more than one hundred cases of nephritis among the refugee children. This preval was due perhaps to the bad conditions under which refugees were living (most of them were in tents or ca and to the extremely cold and damp weather.

I did not have the advantage of a well-equip laboratory, nor enough beds in the hospital, to investig these cases fully, but the following features were not (1) most of the cases were in females; (2) their age usually under 3 years; and (3) commonly they had a course of sulphadiazine in the preceding two weeks inflammation of nasopharynx, otitis media, pneumo or diarrhœa. The diagnosis of acute nephritis based on the presence of œdema and albuminuria with without fever.

In the early cases of this series treatment consisted the start in routine dietetic and diuretic measures, wh had very little effect. When, after fifteen days, the con tion was not greatly improved, I injected 200,000 uni of penicillin once daily for three successive days. T improvement was so striking that I treated subseque cases with penicillin as soon as the diagnosis was made in the majority cure was complete within one week.

This experience contrasts with that of Dr. Fleming But I believe that had he used greater amounts of peni cillin, or subdivided the dose into smaller amounts give at shorter intervals, his results would have been different

Amman, Transjordan.

PURIFIED TOXINS FROM COBRA AND BEE

SIR,—I have developed a technique for preparing in potent amorphous and crystalline form the venom from the cobra (*Naja tripudians*).

The cobra is allowed to bite a rubber membrane covering a small beaker. The venom thus collected, which consists of about 1 ml. of viscid, clear, transparent liquid, is diluted 100 times with physiological saline solution. It is clarified by adding a little aluminium sulphate and lime water; and toxin is then precipitated by the addition of pure acetone. The precipitate is centrifuged, washed with acetone and then with ether, and finally dried in vacuo, leaving the toxin as a white amorphous substance. Alternatively the precipitate may be concentrated by evaporation under reduced pressure at 30°C and the toxin crystallised by drying in vacuo over phosphorus pentoxide. One bite produces 104 mg. of the final crystalline toxin.

This crystalline material is strongly active when injected subcutaneously into rats; 0·03 mg. is sufficient to kill an albino rat of 100 g. body-weight.

A second method of preparation is as follows:

The venom, which is collected as in the first method, is diluted 100 times with $N/10$ hydrochloric acid and is then neutralised with normal caustic soda; a saturated aqueous

---

1. Sevitt, S. *J. Path. Bact.* (in the press).
2. Sevitt, S. *Brit. J. exp. Path.* (in the press).

ı of picric acid is added and the liquid allowed to stand hours. The supernatant fluid is poured off and the ng precipitate containing the toxin is repeatedly ed with 80% acetone in water until no further picrate ered. The toxin is then precipitated as hydrochloride ing a few drops of concentrated hydrochloric acid and ess of acetone to the 80% acetone extracts. The recipitate is centrifuged off, washed successively with e and ether, and kept in vacuo over phosphorus pent- The potency of this toxin, in terms of the minimal dose for the rat, was about 0·03 mg. per 100 g. eight.

resulting purified "toxin" dissolves readily in d water to give a clear solution. With an aqueous n containing 1 mg. per ml., the Millon, xantho- c, and biuret reactions were positive. There was recipitation on boiling or half-saturation with nium sulphate. (Half-saturation with ammonium ate produced a small flocculent precipitate which on-toxic in a solution containing 4 mg. per ml.). oxin was completely precipitated by full saturation ammonium sulphate, by absolute alcohol, and by he. Picric acid gave a precipitate which dissolved ating and reappeared on cooling. The substance's al behaviour was that of a proteose. Burning of ried toxin left no residue.

e Toxin.—I have also prepared toxin from the hive- *Apis mellifica*) in amorphous form, as follows:

sh telsons are mixed with a small quantity of quartz moistened with 1–2 ml. of *N*/10 hydrochloric acid, ground thoroughly in a mortar for about half an hour. finely ground mass is extracted with *N*/10 hydrochloric using 30 ml. at a time. Five extractions are sufficient move all the toxin. The insoluble residue is decanted; the combined decanted extracts are neutralised by ng with normal caustic soda. The toxin is precipitated crate by adding saturated picric-acid solution and allow- the mixture to stand for 24 hours. The clear liquid is nted and the residue extracted with 80% acetone; al extractions are necessary to remove all the soluble ate. The toxin is further converted into a hydrochloride recipitation of the combined extracts through the addition n excess of pure acetone and a few drops of concentrated rochloric acid. The precipitate is centrifuged and red, washed first with more acetone and then with ether, finally dried in vacuo.

hysiology Department, Abbassia Medical
Faculty, Fuad I University, Cairo.

B$_{12}$ DIURESIS

IR,—A rather profuse diuresis frequently attends the ninistration of liver extract to patients with addisonian emia in relapse. Diuresis has likewise been noticed ere the therapeutic agent is crystalline vitamin B$_{12}$. e explanation usually offered for the diuresis of nitting addisonian anæmia—that the hæmatocrit es at the expense of the circulating plasma-volume d that the latter must recede by water elimination— es not accord with the fact that the hæmatocrit (by a reversion of macrocytosis) during l of therapy when diuresis takes place. mission of non-addisonian anæmia is by water retention.

Cobalt, a constituent of vitamin B$_{12}$, is said to have a uretic effect,[1] as does a liver diet instituted for the eatment of nephrosis.[2] One [3] of us had reported profuse iuresis in a uræmic patient given an experimental liver reparation of high reticulocytogenic activity.

Our decision to determine possible diuretic effects of itamin B$_{12}$ in non-anæmic subjects arose from an bservation on an amyotrophic patient who on adrenal- ortex therapy developed water retention. The injection of 15 µg. of vitamin B$_{12}$ in solution was followed by ubsidence of œdema within a few hours in face of the continued administration of adrenal-cortex extract. Subsequent observations on this patient indicated that a possible diuretic effect of vitamin B$_{12}$ should be explored.

Of 16 patients with essentially normal blood pictures who were given 45–75 µg. of the vitamin in a single injection, 12 responded during the ensuing twenty-four hours with what was felt to be an unequivocal increase in urinary output, comparison being made to control periods immediately before and remotely after administration. Of these 12 patients, 1 had amyotrophic lateral sclerosis, 3 chronic glomerulonephritis, 4 addisonian anæmia in remission, and 1 cardiac decompensation; 3 were normal volunteers. Another 2 volunteers and 2 further patients with cardiac decompensation did not show a definite response.

While we have no evidence of the nature of the diuresis induced by vitamin B$_{12}$, a clue to the mechanism may be found in the fact that diuresis has been found to accompany the peripheral vasodilation ("cobalt flush") seen in occasional patients receiving more than the ordinary parenteral dose of B$_{12}$. Le Goff attributed cobalt flush to the sympathomimesis of cobalt salts, and if his explanation is correct one might expect a similar dilation of the glomerulo-afferent arterioles. Purely from speculative considerations, we are tempted to accept Le Goff's explanation because of the entrancing possibility that cobalt or a cobaltoporphyrin is either the prosthetic nucleus of, or a cofactor of, the enzyme cholinesterase. Potentiation or enforcement of the enzyme might be a mode of sympathomimesis.

Whatever the explanation of cobalt or B$_{12}$ diuresis, the latter does not seem to be contingent upon changes in hæmatomorphology. Possible clinical utility of B$_{12}$-induced diuresis might be worthy of investigation.

RADIOTHERAPY IN LEUKÆMIA

SIR,—Your annotation of Oct. 1 suggests, at least by implication, that the most valuable method of treatment of chronic leukæmia is irradiation, although admittedly, as an afterthought, there is a suggestion that nitrogen mustard may be as efficacious.

In my opinion it is of the utmost importance to realise that arsenic administered by mouth is one of the most valuable—perhaps the most valuable—method of treatment of early cases. It is of course well known that every method of treating leukæmia loses its efficacy sooner or later. It is therefore important to employ the mildest method which will produce a good result, even if its effect is slowly manifested. Admittedly the radiotherapist can produce remarkable changes in the physical signs and in the blood picture in cases of chronic leukæmia, while often greatly improving the patient's health; but when his method of treatment fails, there are no other "shots in the locker." If, however, treatment is started with arsenic, health may often be preserved for months or even years before radiotherapy becomes essential.

It is peculiar that the fashion for using arsenic varies so much from time to time. Naegeli advocated its use as the main standby in the treatment of chronic leukæmia, but then the rise of radiotherapy caused it to be relegated to a very secondary position. In 1931, Forkner and Scott[1] again made arsenic a popular therapeutic agent, but today the impressive complexity of radiotherapeutic technique and the quick (although usually transient) results undoubtedly have caused many people to take the retrograde step of commencing treatment with irradiation.

I would be prepared to state categorically that for chronic myeloid leukæmia, where the patient's general condition is reasonably good, the correct treatment is *graduated doses of Fowler's solution by mouth; and in* such a case it is wrong to start treatment by irradiation earlier than is absolutely necessary.

EFFECT OF COOLING ON "SPREADING" ACTION OF HYALURONIDASE

SIR,—In the course of our studies on the anti-hyaluronidase action of gentisic acid, various observations caused us to consider the possibility that the in-vivo action of the enzyme could be influenced by local modification of the body-temperature.

Using the Duran Reynals method of intradermal diffusion of a dye, we observed in adult white rabbits which had been previously depilated that local cooling of the skin with an ice-bag increased the "spreading" effect of hyaluronidase to the extent of 50–70%. The application of a bag filled with water at room-temperature or heated to 45°C had no detectable effect. In all cases control observations were made on the opposite side.

This effect could be due to the vasoconstrictor action of cold and to the consequent local diminution of the serum anti-hyaluronidase substance.[1] In our belief the phenomenon might explain why, in the origin of the common cold, cooling favours penetration by the virus.

P. PUIG MUSET
J. A. SALVA
F. G.-VALDECASAS

THE REGISTRAR'S SALARY

SIR,—You must surely be wrong in your admonition to Dr. Gee (Sept. 24). He has done no more than protest at the injustice of being yet unable to earn a living after a decade devoted to the study of medicine. The bland statement that things have ever been so is the most maddening complacency a young man can meet. It is sad to have it come from the Editor of THE LANCET.

I admit that in the past the young specialist has always had a lean time until he became established. In the past children were driven to work in factories but we do not regard that precedent as hallowed today. Moreover a change has occurred in the essential nature of the process of specialisation. In former times the trainee specialist looked forward to a very splendid reward for his asceticism. A Rolls-Royce, consulting-rooms in Harley Street, and a fine country home were his in the fullness of time by the exercise of reasonable diligence and intelligence. We regret the departure of these pleasant prospects from the order of things; but not excessively. We should settle very gladly for a modest security now.

Surely the most pertinent reason today for specialising is individual interest and ability. I just do not happen to have the type of mind that can pass with interest and satisfaction from an intestinal carcinoma to a cut finger, from a howling baby to a malingering workman. I envy those whose natures are thus constituted but fail to see why I should be penalised for my single-mindedness.

Very nearly every week one or another of your correspondents points out, "what is wrong with British medicine." I have very seldom seen the same thing blamed twice. By now the range of the fons et origo mali must be staggering. I should bet Mr. Bevan leads by a short head, but I should like to add one to the list —old men. In all humility I submit that British medicine today is carrying an intolerable burden of old men—men whose imaginations have atrophied with the passage of years. Men who, inter alia, say blandly; "I had a hard time before I became established. Good healthy discipline for these young pups to work their way up, through the lean years." They have quite forgotten the bitterness of those lean years. If they ever knew, they *gotten the humiliation of the tawdry devices* one lives when one's social and intellectual higher than the financial. Besides, the world they cope with and the one we live in are really di The majority of them had private means; the m of us are engaged in the disreputable pursuit of h ourselves up by the boot-straps. We have lost the of the war and are older. Very many of us have and children; and many more should, for we are a valuable class. If the old men have their way, children of those of us who do propagate will be exh products.

I have a deep respect for the clinical acumen wisdom of my teachers, many of whom helped fram scales that govern our living today. But it needs to said quite bluntly that they have been lacking in hu understanding. Was there, on any one of the innumer *committees that sat to determine our fate*, one houseman or registrar? Or even one man under Almost certainly not.

It is sad to have THE LANCET wag an atrop grandfatherly finger at us. Perhaps you might recon relent, and turn to plead our cause?

British Hospital for Mothers and Babies, London, S.E.18.

ARNOLD KLOPP

SIR,—Dr. Lipscomb has written a good ar (Sept. 17). The correspondence arising out of it is more interesting. But the registrar is not the impor man in the team; he is the nonentity. Proof of this will find in the way he is paid, for his gross is ab one-third of the figure that Spens said the gen practitioner should expect net at 1939 values.

In deciding to abandon hospital, Dr. Gee (Sept. must have realised this, but he may find himself *more happily placed in general practice* in the new or Lip service used to be paid to the family doctor; transferring it to the registrar there must be some ou but I cannot read it. Will the registrar develop imp tance, with reward in proportion, or will he be another cog in a wheel with an enormous number cogs—a well-trained member of the chorus in the seco row?

A. ROTHWELL.

Salford.

PENICILLIN IN THE CEREBROSPINAL FLUID

SIR,—In their article last week Dr. Redfearn and colleagues showed that when penicillin is injected intr muscularly in sufficiently high dosage it is able to pen trate the uninflamed blood/cerebrospinal-fluid barri They mention that previous demonstrations of th ability of penicillin to enter the cerebrospinal fluid hav been criticised on the grounds that the permeability the barrier might have been increased by abnormalit —e.g., syphilis—in the patients studied.

This calls to mind certain observations made by m colleagues and myself in Liverpool some years ago. We also found, in the rabbit and in man, that penicill is able to breach the normal blood/cerebrospinal-flui barrier if it is administered intramuscularly in sufficie dosage. For the observations in man (though admittedly in only 3 subjects) we purposely chose cases of uncom plicated gonorrhœal urethritis, and not of syphilis, that a normal barrier might safely be assumed.

In regard to the treatment of syphilis, Eagle and Musselman[2] claimed that penicillin blood-concentrations above a very moderate *threshold-level* are no more spirochæticidal in vitro than at that level. This work is often quoted as establishing the futility of high doses of penicillin for the treatment of syphilis. Nevertheless we have advocated massive dosage, and our observations

penetration of penicillin into the normal cerebro-
luid formed part of the experimental evidence on
ur arguments were based. Merely for reasons of
ence and accessibility, the intrathecal space was
as a representative of those tissue-spaces in
which might ordinarily not be reached by peni-
dministered in moderate doses. The fact that it
ly after massive dosage that penicillin could
ate into the cerebrospinal fluid was therefore
t forward to support the case for such dosage
tages of syphilis, "since the organisms are to be
ed not merely in the circulating blood but also
nanner of extravascular sites to which they may
ained access."

tment of Pharmacology, Oxford. E. M. LOURIE.

REATMENT OF ACCIDENTAL ARSENICAL POISONING WITH DIMERCAPROL

—Dimercaprol (BAL) now has an established place
treatment of toxicity from parenterally adminis-
arsenical compounds. The following account of
e of the drug to treat acute arsenical poisoning due
swallowing of arsenical cattle-dip may be of interest.

arty of 13 African women was working by the side of a
making bricks to be used in building a tank for
g cattle. To make the brick clay into the proper
tence for placing in the brick moulds, water was being
d up from the stream in a number of receptacles—
used cattle-dip drums of about 4-gallon capacity.
about 10 A.M. it was getting hot, and one of the women
ent to the stream to fetch water for drinking. For this
ook a dip drum which was empty but had not been
d and scrubbed. She washed the drum in the stream
perfunctory way and brought the water to the brick-
ng site. where all the women slaked their thirst.
hin a few minutes the whole party was vomiting. and
n half an hour 2 of the women were collapsed. They
ed that they had been poisoned and sent for help.
were many miles from the nearest telephone and about
les from the hospital, which they did not reach until 5 P.M.
admission 11 of the women. though still vomiting and
laining of abdominal pain. were able to walk and to
a clear history, and were obviously recovering. In hospital
vomiting soon grew less. and they continued to improve.
remaining 2. however. were completely collapsed. It was
n that they were the last to drink from the drum, and
umably they drank the dregs. Each complained of
ea and vomiting. violent abdominal cramps. pains in the
and precordial pain. They cried out with each spasm of
; so. in view of the usual African stoicism. the pain must
been very severe indeed. Their skin was cold and grey:
r conjunctivæ were suffused and their tongues dry; and
r pulses were feeble.
was decided that in view of the delay since the arsenic
been consumed there was little point in washing out the
nach; detoxication was the urgent need. The patients
e kept warm and nikethamide was given subcutaneously.
ercaprol was given in 2 ml. doses intramuscularly three
es at four-hourly intervals—i.e., at 5.30 and 9.30 P.M. and
1.30 A.M.
Next morning the general condition of both patients was
ch improved; they were no longer collapsed. vomiting
d ceased, and the abdominal pains were only occasional
d fleeting. Twenty-four hours afterwards they were fully
overed and were out of bed: and the next day they
ounced that they were well and insisted on leaving hospital.

The drum from which the women had drunk was
ught in for inspection. It was clearly marked "cattle-
p." The liquid in the bottom was dark brown and
d the characteristic odour of cattle-dip.

Cattle-dip consists of a solution or emulsion of arsenite
soda to which has been added some substance such as
loes to prevent the cattle drinking it. In concentrated
olution in the drum the sodium-arsenite content is
bout 80%—or 64% expressed as arsenic trioxide. For
ipping cattle to kill ticks, the concentrated solution is
iluted 1 in 400 so that the final solution contains the
quivalent of 0·16% arsenic trioxide. There seems little doubt that the two women who were seriously ill must have ingested a very large dose of arsenic.

Where there is any delay between the accidental swallowing of arsenic and the institution of first-aid measures, such as washing out the stomach, dimercaprol would seem to be a very useful drug for countering the effect of the absorbed arsenic, giving results no less dramatic than in poisoning arising after parenteral administration of the organic arsenicals.

Concession, Southern Rhodesia. D. A. W. RITTEY.

LEAD NIPPLE-SHIELDS

SIR,—I have read with interest and great care your leading article last week and the article by Dr. Gordon and Mr. Whitehead. The embargo by the Ministry of Health on the sale of lead nipple-shields must be a source of satisfaction to you, since you recommend their abolition. Has it occurred to you that a valuable aid to breast-feeding has thus been abolished, and is this also a source of satisfaction?

In certain cases lead nipple-shields are a unique aid to breast-feeding: they have enabled me to feed each of three babies for a normal period of nine months, when all other remedies had failed to relieve severely cracked nipples. For a fourth child, the Ministry's embargo will compel me to wean at a few days old.

I see no justification for such action in Dr. Gordon's article. In the case cited he expressly states that the mother used lead shields continuously without washing her nipples before each feed. This only justifies a warning that scrupulous cleanliness is necessary when using lead shields. The possibility of lead deposits being absorbed and then excreted with the milk is a mere suggestion which, Dr. Gordon states, he has never investigated.

The letter in your columns from Dr. Mackay and Dr. Hunter yields even less precise evidence. They assert that the use of lead shields necessitates a meal of lead for the suckling child. Have they never heard of the simple precaution of washing? The suggestion that plastic shields can replace lead ones is frivolous; no-one who has observed the effect of lead shields with intelligence can doubt that the deposits from the lead are a valuable part of their healing power.

"The facts" of this controversy are more teasing and elusive than you or your correspondents indicate. May one hope that the humility which should inform all research may lead you to investigate the matter further?

Pilton, Barnstaple, Devon. JOAN S. BLACKSELL.

Public Health

Setback in Scottish Campaign Against Diphtheria

IN Scotland the campaign for protection against diphtheria has suffered a serious setback. The October number of the *Health Bulletin* issued by the Department of Health contains an analysis showing that at the end of 1948 51·4% of preschool children and 73·4% of school-children were protected. (About 12–13% of babies in the preschool group are too young for inoculation.) Both these percentages are higher than a year before: but in the second half of 1948: (1) the number of preschool children inoculated fell somewhat: (2) the number of school-children inoculated fell dramatically to a much lower level than in any six months since the campaign started; and (3) the number of reinforcing doses given fell to just over half the number in the previous six months.

Nothing, says the bulletin, has happened to discredit immunisation, and the disease is not yet so rare as to delude the public into believing that protection is unnecessary; moreover, there has been no great change in central propaganda.

During 1948 there was increasing shortage of local-authority personnel—"a shortage which, in the case of medical staff, was intensified by a number of health officers obtaining appointments under regional hospital boards." That this shortage largely explains the decline in the number of inoculations has been corroborated by comparing local figures for inoculations with those for staff.

> "The highly significant association between dwindling numbers of inoculations and increasing shortages of assistant medical officers of health implies either that the two items are causally related or that both are due to some common cause; but the causes of the shortage of public-health doctors are well enough known—depletion of existing complements by retirals and by doctors quitting the field of public health, and difficulty in obtaining doctors with qualifications to fill these vacancies. Hence it must be concluded that an important cause of the decline in the number of inoculations is shortage of public-health doctors."

During 1948 diphtheria cases in Scotland numbered 723—the lowest total ever recorded. The number of deaths was 31—just under 6% of the number in 1941.

Higher Mortality from Rheumatic Fever

Earlier this year we heard of an impression among pathologists that the number of necropsies on cases of *acute rheumatic fever was increasing.* We consulted the General Register Office, which has kindly supplied the following figures for deaths from rheumatic fever in England and Wales during the years 1946–48:

Age, years	*Males* *1946*	*1947*	*1948*	*Females* *1946*	*1947*	*1948*
0–	1	nil	nil	1	1	3
1–	7	5	15	10	11	11
5–	28	30	31	31	38	41
10–	45	41	42	36	47	53
15–	26	21	25	17	18	25
20–	15	10	9	13	14	22
25–	6	12	7	13	11	8
30–	2	13	5	7	11	13
35–	7	12	12	15	14	7
40–	10	8	8	9	8	10
45–	10	9	9	10	5	11
50–	4	5	6	6	4	6
55–	5	5	9	8	8	7
60–	4	5	8	7	1	3
65–	nil	4	7	1	10	6
70–	1	4	2	nil	1	5
75–	1	3	5	1	2	6
80–	nil	nil	2	nil	1	nil
85–	nil	1	1	nil	1	nil
All ages	174	188	206	188	206	210

The death-rates from this cause per million population for certain groups were as follows:

Year	*Under 15 years,* *Male*	*Female*	*Male and female*	*15–25 years, Female*
1946	18·1	18·1	18·1	9·9
1947	16·3	21·7	19·0	10·8
1948	19·1	24·3	21·7	16·0

For the forty years ending 1892 the mean death-rate from rheumatic fever was about 87 per 1,000,000—seven times that of 1942. In 1901 the crude death-rate per 1,000,000 was 67, and by 1913 it had fallen to 48.[1] Since 1925 the rate has fallen more or less steadily. The following tables give the figures for deaths in each year from 1928 to 1938,[2] and from 1938 to 1948[3]:

	Year *1928*	*1929*	*1930*	*1931*	*1932*	*1933*
Males	638	638	693	557	491	589
Females	862	779	812	703	627	718
Total	1500	1417	1505	1260	1118	1307

	Year *1934*	*1935*	*1936*	*1937*	*1938*
Males	594	526	535	395	511
Females	793	649	607	522	644
Total	1387	1175	1142	917	1155

	Year *1938*	*1939*	*1940*	*1941*	*1942*	*1943*
Males	490	427	349	298	218	254
Females	614	527	491	333	275	399
Total	1104	954	840	631	493	653

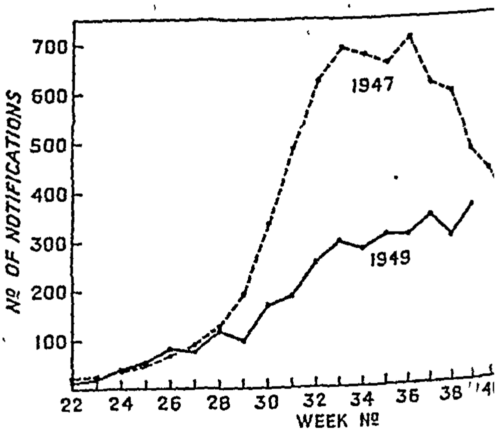
	Year *1944*	*1945*	*1946*	*1947*	*1948*
Males	290	256	174	188	206
Females	328	281	188	206	210
Total	*618*	*510*	*362*	*394*	*416*

It will be seen from these figures (which non-civilian males from Sept. 3, 1939, and non females from June 1, 1941) that though the annı of deaths has risen during the past two y remains below that for 1945.

During the late war, Glover,[1] who drew atte the parallelism between the death-rates from fever and rheumatic fever, suggested that the co decline in deaths from rheumatic fever might be to improved environmental conditions than to a relation between man and *Streptococcus pyoge* will be recalled that by regulations[4] made two y acute rheumatism is notifiable in Lindsey (Linc and in Bristol, Grimsby, Lincoln, and Sheffiel perhaps the epidemiological study which these re have made possible will help to explain the setback. Though more sustained, this is not as that suffered between 1942 and 1943; and possible that, as in *1944, the interrupted dec* be resumed.

Poliomyelitis

During the week ended Oct. 1 notifications in and Wales were: poliomyelitis 331 (268) encephalitis 26 (27). The numbers for the week are shown in parentheses. As the accon figure shows, these are the highest weekly t



Notifications of poliomyelitis and polioencephali

year. In 1947 the totals for the correspond were poliomyelitis 441, polioencephalitis 32.

Multiple cases (poliomyelitis and polioen together) were reported from the following London 44 (48), Bedford 5 (1), Berkshire 5 (3), ham 2 (1), Chester 4 (7), Cornwall 8 (8), Dor Durham 3 (1), Essex 26 (17), Gloucester 17 (0), 12 (7), Kent 19 (18), Lancaster 41 (24), Leices Norfolk 4 (2), Northampton 4 (4), Northumberla Nottingham 9 (9), Somerset 6 (7), Southampt Suffolk, East 2 (5), Surrey 9 (11), Sussex, Ea Warwick 13 (8), Wiltshire 8 (9), Yorks, Eas 3 (1), Yorks, North Riding 2 (1), Yorks, Wes 38 (19), Glamorgan 6 (3), Monmouth 2 (0).

Insurance Against Tuberculosis

Whether tuberculosis in nurses and othe workers should be a "prescribed disease" u National Insurance (Industrial Injuries) Act considered by the industrial diseases subcom the Industrial Injuries Advisory Council. Per bodies interested in this question are invited t written evidence, not later than Dec. 1, to the secretary, Mr. F. K. Forrester, Ministry of Insurance, 6, Curzon Street, London, W.1, fro an explanatory memorandum may be obtained.

---

1. Glover, J. A. *Lancet*, 1943, ii, 51.
2. Registrar-General's Statistical Review of England and Wales for the Year 1938. Tables. Part I. Medical. H.M. Stationery Office, 1940.
3. The figures for the years 1938–47 are taken from the Registrar-General's Statistical Review for 1947. The criteria differ slightly from those used in compiling the figures for 1928–38; and this accounts for the difference between the two tables in the number of deaths in 1938.
4. See *Lancet*, 1947, ii, 394, 409.

Obituary

MAJOR GREENWOOD

D.SC. LOND., F.R.C.P., F.R.S.

Major Greenwood, professor emeritus of epidemio- nd vital statistics in the University of London. n Oct. 5 at the age of 69.

father and his grandfather both practised medicine East End of London, and he shared, rather ntly, their unusual Christian name, which he red to abbreviate to its initial letter. An only he grew up in an intellectual home, for his father ot only a doctor and deputy coroner but also a f learning and a writer, while his mother was a ian and a linguist. From Merchant Taylors' l he went with a Buxton scholarship in 1898 to sity College, and later he completed his medical s at the London Hospital, whence he took the int qualification in 1904. For some months he as assistant to his father, but became demonstrator in physio- t the London under Sir Leonard with whom he collaborated n investigation into caisson se. Later he declared that these years made him the kind of r he became. "As a boy," he . "I lived in the atmosphere n East End general practice: very young man I spent four y years as the assistant of a great physiologist." But he already attracted to statistics. in 1910, the year in which he appointed statistician to the er Institute, his publications on Physiology of the Special Senses on Factors which Influence the uency of Infection showed the d of his development. He used y that though he had always d sums he was no mathematician. that as it may, Karl Pearson his *Grammar of Science* turned enwood into a statistician, and application of statistical methods edical research was to remain the f interest of his life.

[Vernon

During the first world war he served in the R.A.M.C., h the rank of captain, till in 1917 he was put in charge the medical research subsection of the Ministry of mitions. In 1918, with Udney Yule, he wrote the dical Research Committee report on causes of wastage munition factories, and his investigations with E. L. llis and May Smith into fatigue and other industrial blems were continued through his work for the dustrial Health Research Board. *Health of the dustrial Worker*, which he wrote jointly with Collis, peared in 1921, and in 1935 in his Heath Clark lectures discussed the temperamental factor in industry.

In 1919 he was put in charge of the division of medical atistics of the new Ministry of Health, a post he held til 1928 when he was appointed to the chair at the ndon School of Hygiene, where he remained till his tirement in 1945. Here he brought statistics to the aid bacteriology, and with the late W. W. C. Topley and devoted team of investigators, through the study of perimental mouse epidemics, he attempted to create "grammar of the language of epidemiology." This ork he described in his Herter lecture in 1931, in *pidemics and Crowd Diseases* (1935), in *Experimental pidemiology* (a report made to the Medical Research ouncil in 1936), and in a *Statistical Study of Infectious Diseases* (1946). Alike by investigation, by teaching, y advice, and by criticism, he exercised over con- mporary medicine a strong and astringent influence which is far from being exhausted.

In his presidential address to the epidemiology section of the Royal Society of Medicine he described the early years of the General Register Office, and his veneration for the early workers in his own field, especially Farr, led him to study other medical worthies. The *Medical Dictator* (1936) also contains essays on Galen, Freind, "Heart" Latham, Pierre Louis, and Osler. His style was lucid and pungent and if he sometimes found human nature to be frail his estimate escaped him in the guise of quotation and quip. Last year he published some *British Pioneers of Social Medicine*—another set of Heath Clark lectures—celebrating the centenary of Simon's appointment as medical officer of health for London.

His work during the 1914–18 war on the Liquor Control Board was less well known than his other activities. As one of the original members of the Academic Assistance Council (which later became the Society for the Protection of Learning) he also had continuous experience of the plight of displaced scientists, and during the late war he wrote wisely and generously on behalf of the medical refugees who sought work here in their own profession.

The list of his academic honours is formidable. In 1922 he delivered the Milroy lectures to the Royal College of Physicians and in 1924 he was elected F.R.C.P. In 1927 he was awarded the Buchanan medal of the Royal Society and the following year he was admitted to their fellowship. From 1934 to 1936 he presided over the Royal Statistical Society, which he had served for the previous 15 years as secretary. In 1945 he received their Guy medal in gold. He was also an honorary member of the American Statistical Association and the Indian National Academy of Science and a member of the International Statistical Institute. From its inception he was chairman of the statistical committee of the Medical Research Council.

Greenwood will always be gratefully remembered by early research-workers who often found themselves struggling with problems little understood even by members of the committee theoretically responsible. And if he won recognition for his specialty he held a balanced view of its scope. As early as 1924 he wrote:

> "When I first took an interest in these matters, more than twenty years ago, there was some tendency to treat the statistician or biometrician as a pariah, and he acquired the virtues and vices of a minority, a certain courage and a certain trick of overemphasis. Now statistics and statisticians are perfectly respectable; there may even be a risk of putting the claims of the statistical expert too high . . . the statistician must be the equal not the predominant partner."

Nor did he expect to accomplish overmuch among the unstatistical. For instance in 1930, when opening a discussion on vaccination, he admitted that he did not hope "to alter the settled convictions of any one of his audience by statistical reasoning." But in his last paper in our columns, on Simple Statistics of Cancer, he suggested that "even a busy surgeon allergic to algebra" need not find the principles of random sampling too difficult to master.

M. S. adds: "Professor Greenwood enjoyed a verbal fight and was never deterred by the possible unpopularity of his point of view. His defence of the psycho-analysts at a time when within and without the medical profession they were somewhat unscrupulously attacked was a masterpiece of pungent writing. As a teacher he spared no pains in the preparation of his lectures. Matter, form, and delivery were an inspiration to the brighter students, and even those who failed to grasp his point of view recognised him as a great personality. He had an amazing memory and could quote almost verbatim from any book he had read. He loved the classical writers particularly Virgil, but he was familiar with medieval and modern writers and within a few minutes he might casually quote from an obscure Latin work, from Thomas Aquinas, Marx, or some detective story read years before.

The earlier statisticians were never mere mathematicians to him but always human beings.

"As a critic he was just, but at times he failed to realise that a great gulf often separated his knowledge and ability from those of lesser people. As the head of a department he was kindness itself; for any one in trouble he would do all he could and he usually did it unobtrusively but efficiently. Among those who knew him best he inspired affection, but those who rarely came in contact with him were more than a little in awe of him. He suffered from occasional fits of depression and it was during these periods that he was difficult to understand. Once he said of himself that he spent much time in encouraging self-distrustful people who envied him his confidence and readiness, whereas he toiled very hard to do the things that looked easy. His own alternating moods gave him a deep insight into some of the writers he studied—perhaps in particular Galen. He died as he would have wished, at work."

Dr. Greenwood married in 1908 Rosa Baur, who died in 1945. They leave two sons.

Diary of the Week

OCT. 16 TO 22

Monday, 17th

UNIVERSITY OF LONDON
5.15 P.M. (*University College, W.C.1.*) Prof. J. Z. Young, F.R.S.: Structure of Peripheral Nerve. (Last of two lectures.)

acquired, in the course of long years of devoted collabora
with him, something of Hunter's own look.

MALARIA IN BRIEF

THE Ministry of Transport's *Suggestions for the Preven*
Diagnosis, and Treatment of Malaria,[1] intended for s
surgeons, supersedes a Ministry of Shipping memoran
issued in February 1941. The chief differences bet
the two are due to the introduction of 'Paludrine';
there are other useful changes. Thus "prophylaxis"
become "suppressive treatment," and in the part on cli
manifestations a section on atypical attacks has been ins
between those on typical and pernicious attacks; and
are added sections on relapses, malaria in children,
malaria in pregnancy—all very useful.

It must always be difficult to draw up such a brief acc
of the most protean of all diseases, and on the clinical
it is doubtful whether this can be bettered. Two impo
principles are printed in italics. The first is: "It (ma
may simulate or be simulated by any other disease kno
medical science." Those who have had no experience of m
in the wilds, afloat or ashore, away from any recognised ma
service, find it hard to appreciate this but it is broadly
The second is: "Malaria may complicate or be complicat
any disease (medical or surgical) known to medical scie
This may be obvious but is often forgotten. Under "G
Precautions" a list of administrative arrangements is
which if carried out to the last letter would prevent a
on board ship ever catching malaria. The first two, how
on which the rest hang, are not suggestions to ships' surg
They could only be carried out by arrangement at the h
level between Ministry, owners, and merchants at eithe
of the voyage.

This excellent pamphlet should not be kept only f
ship's surgeon. It should be issued, free of charge, to the
of every medical school for him to pass on to the teach
tropical medicine, for it will give the student as much pra
information in shorter space than any textbook, gene
special. The dean should also have copies to hand to the
qualified man going to any place where malaria m
encountered. The various "tips" included in these
do not all find their way into a textbook but are pr
what the newcomer to the tropics wants when treati
first cases.

A NEW SCANDINAVIAN JOURNAL

ations." Despite alarm at the growing number of , most will agree with the editors that this particular is required to complete the range of subjects covered Scandinavian literature; and we welcome the appear- what promises to be another well-edited and pleasing al from this quarter of Europe. The first number s nine articles in English, mostly on biochemical and a technical section which is to be devoted to ory organisation and construction and the training ratory personnel. The articles in the first issue include ble one on the Complete Porphyrin Analysis of Patho- Urines by S. L. Sveinsson, C. Rimington, and H. D. . The foreign subscription rate is Kr. 35 per annum.

PAVLOV FILM

centenary of Pavlov's birth is being celebrated this nd through the good work of the Society for Cultural ons with the U.S.S.R. and of the British Film Institute, n *The Mechanism of the Brain* has been copied on to . gauge to make it widely available. Made in 1925, a silent film in six reels, lasting nearly 1½ hours, and is able from National Film Library, 4, Great Russell , W.C.1. After noting that more complex behaviour ds on a more complex brain (reel 1), the transmission of ses by nervous tissue is shown (reel 2), then various les of absolute reflexes and conditioned reflexes (reel 3). ion of cerebral cortex suppresses function on the opposite f the body (reel 4). Reel 5 shows the production and tion of conditioned reflexes in children, the differentiation ilar stimuli, and the effects of agenesis and disease of rain. In reel 6 are shown reflexes of the child at birth as he grows older. The end of the film refers to the t" reflex, which urges man to achievement. The film, ich further particulars may be had from the Scientific Association, is still of great interest and is likely to e useful to teachers of physiology.

"FOR THOSE ABOUT TO MARRY"

a small leaflet with this title the Family Planning ation have set out simply and acceptably some facts t sex relations which young married couples should know. es (6*d.* each, postage 2½*d.*) are obtainable from the ation, 69, Eccleston Square, London, S.W.1.

---

versity of London

r. Erwin Stengel has been appointed to the university dership in psychiatry at the Institute of Psychiatry.

r. Stengel took his M.D. in 1926 at the University of Vienna re he later held a readership in psychiatry and neurology. In he obtained the Scottish Conjoint qualification. Since leaving na he has held a research fellowship in psychiatry at the ersity of Edinburgh and the directorship of clinical research at nwell Hospital, Chichester. At present he is physician to Bethlem Royal and Maudsley Hospitals. He has published ers on the Ætiology of Fugue States, Air-raid Phobia, and ssional Neurosis and Psychotic Reaction Types.

yal Faculty of Physicians and Surgeons of Glasgow

At a meeting of the faculty on Oct. 3, with Dr. W. R. oigrass, the president, in the chair, Mr. L. S. Scott was mitted to the fellowship qua surgeon.

ciety of Apothecaries of London

Ten postgraduate lectures on modern therapeutics will given in the hall of the society, Black Friars Lane, E.C.4, ing December. Further particulars will be found in our vertisement columns.

ociety of Anæsthetists of South Wales

At a meeting of this society to be held at the Park Hotel, ardiff, at 7 P.M. on Nov. 4, Dr. John Gillies will give an dress.

ondon County Medical Society

A clinical meeting of this society will be held at the Mary ington wing of the Whittington Hospital, Highgate Hill, N.19, on Nov. 2, at 3 P.M.

West London Medico-Chirurgical Society

Mr. V. B. Green-Armytage will deliver his presidential ddress to this society on Friday, Oct. 21, at 8.30 P.M., at the South Kensington Hotel, 41, Queen's Gate Terrace, S.W.7. He has chosen as his subject the Dramatic in Gynæcology and Obstetrics.

Royal Dental Hospital, London

The annual clinical At Home will be held at the hospital on Saturday, Oct. 29, at 3 P.M. The departments will be open for inspection from 9.30 A.M. onwards, and at 12.30 P.M. Dr. Lilian Lindsay will open the Stoke memorial library.

Royal Appointments

Dr. J. N. Loring has been appointed apothecary to the King and to Queen Mary, Princess Elizabeth, and the Duke of Edinburgh. Sir Frederick Hewett has been appointed extra surgeon apothecary to the King and to Queen Mary. Sir James Walton has been appointed an extra surgeon to Queen Mary, and Dr. G. C. Birt, L.D.S., an extra surgeon dentist.

Physiotherapists Association

On Monday, Oct. 17, Dr. Louis Moss will give a lecture on a New Treatment for Chronic Rheumatism by the Use of Adrenaline Cream, and on Wednesday, Nov. 23, Dr. Philip Ellman will speak on the Place of Physical Medicine in General Practice. Both lectures will be given at Charing Cross Hotel, Strand, London, W.C.2, at 8 P.M.

Scottish Committee on the Welfare of the Disabled

This committee of the Scottish Council of Social Service is holding a conference, on the Disabilities of Organic Nervous Disease, in the Lesser City Hall, Perth, on Friday and Saturday, Nov. 4 and 5. Speakers will include Dr. G. W. Ireland, Dr. J. B. Gaylor, Dr. J. Romanes Davidson, and Mr. Joseph Schorstein, F.R.C.S.

Agricultural Research Council

Mr. K. Mather, F.R.S., professor of genetics in the University of Birmingham, Dr. S. Zuckerman, F.R.S., professor of anatomy in the University of Birmingham, and Mr. G. F. Marrian, F.R.S., professor of chemistry in relation to medicine in the University of Edinburgh, have been appointed members of the council in succession to Prof. T. G. B. Osborn, Sir John Simonsen, and Mr. W. J. Wright, whose terms of office have expired.

W.H.O. in South-East Asia

The W.H.O. Regional Committee for South-East Asia has made a series of decisions which are expected to lead to greater coöperation among countries in this area. Delegates from India, Afghanistan, Burma, Ceylon, Thailand, and French and Portuguese India have agreed on plans to pool national resources for training health workers; to manufacture essential medical supplies, such as D.D.T. and penicillin, within the region; to approach the United Nations Economic Commission for Asia and the Far East for assistance in obtaining materials for housing projects; and to exchange information on public-health work. The committee also approved a recommendation that top priority should be given to extending the B.C.G. vaccination programme and to creating a national tuberculosis training centre in a country of the region.

Executive Councils' Association

At the fifth meeting of the management committee of this association on Sept. 9 the subjects discussed included the following:

Branch surgeries in rural areas.—In reply to a suggestion that executive councils should be authorised to provide these surgeries, recovering the cost from the practitioner over an extended period, the Minister of Health had replied that he considered the provision of adequate surgery accommodation to be the responsibility of the practitioner providing general medical services and not of the executive council. A fund similar to the special subsidy portion of the insurance mileage fund was not available. He suggested, however, that the doctor might apply for an inducement payment to help meet exceptional cost. It was not intended that capital expenditure should be provided in this way, but a regular annual payment might be made in consideration of the extra expense involved in providing and maintaining a village surgery.

[illegible] *practitioners on medical advisory com- [illegible]nent committees.*—A resolution was sub- [illegible]ing that as specialist representation was provided on these advisory committees there should also be direct representation of general practitioners and that all proposals for the organisation of hospital services should be submitted to the local medical committee for observation. "Suspicion, misunderstanding and ill-will" were in danger of being engendered by the existing situation.

Supplementary ophthalmic services.—It was stated that the Minister was considering the suggestion that, in view of the heavy demands on these services, opticians might be allowed to repair or replace glasses without requiring the applicant to undergo a further sight test.

The second annual meeting of the association will be held at Bournemouth on Oct. 20 and 21.

McGill University, Montreal

Dr. A. S. V. Burgen, demonstrator in pharmacology at Middlesex Hospital medical school, has been appointed to the chair of physiology in the university.

Physiology of Vision

Prof. Hamilton Hartridge, F.R.S., in his series of lectures on this subject, will give the fourth part, dealing with the retina, on Oct. 24, 25, 26, and 27. The lectures, which are free, will be held at Gresham College, E.C.2, at 5.30 P.M.

University of London World Government Movement

Prof. R. J. V. Pulvertaft will take the chair at the meeting of this body which is to be held at 6.30 P.M. on Monday, Oct. 17, at the Union Assembly Hall. Further information and tickets may be had from J. H. Clark, King's College Hall, Champion Hill, S.E.5.

Social Psychotherapy Centre

Last week the first of ten lectures entitled Introduction to Social Psychiatry was given at the centre, 7, Fellows Road, London, N.W.3. They will be held weekly on Wednesdays at 5 P.M., till Dec. 14. The speakers include Dr. Joshua Bierer, Dr. E. N. Snowden, Dr. A. R. Redfern, and Dr. A. Joyce Martin.

Hormone Assay

Prof. J. H. Gaddum, F.R.S., will take the chair at a symposium on this subject to be held by the biological methods group of the Society of Public Analysts and other Analytical Chemists and the Society for Endocrinology at 11, Chandos Street, London, W.1, on Thursday, Oct. 20, at 2.15 P.M. The speakers will include, Dr. H. O. Schild, Dr. G. F. Somers, Mr. K. L. Smith, Dr. J. A. Loraine, Mr. G. A. Stewart, and Dr. P. M. F. Bishop.

Free Medicine Scheme in Australia

The Melbourne correspondent of the *Times* (Oct. 8) reports that the High Court, by a majority of 4 to 2, has declared invalid section 7A of the Pharmaceutical Benefits Act, requiring doctors to use a prescription form supplied by the Commonwealth government when prescribing free medicine. The ground for the judgment was that it was a form of civil conscription, which is forbidden by the constitution. Senator McKenna, the minister for health and social services, has announced that doctors willing to prescribe on the official form will continue to do so. He is to ask the Cabinet to consider alternative courses to ensure the supply of free medicine.

Increased Cost of New Zealand Medical Benefits

Anxiety over the growing cost of medical benefits under the social-security scheme has been expressed by the New Zealand ministry of health in its annual report to Parliament. The cost of the services, including upkeep of hospitals, doctors' and dentists' fees, and medicines, is reported by B.U.P. to have risen from £2,435,000 in 1941–42 to £7,843,000 in 1948–49. Between 1942–43 and 1948–49 the cost of doctors' fees has risen from £1,016,000 to £2,306,000, and the cost of free medicines from £563,000 to £1,793,000. The ministry admits that some expenditure is wasteful and unnecessary; and the report announces that a disciplinary committee of practising doctors is to be set up to stop doctors abusing the scheme.

The President's Plan for Medicine

Mr. Oscar Ewing, federal security administrator, has suggested that in the long run President Truman's national health insurance programme would actually prevent the socialisation of medicine. Mr. Ewing, who was speaking in New York, is reported by B.U.P. to have said that almost half the population could not fit ordinary medical care into the family budget. The President's plan was opposed by medical groups, who proposed voluntary health insurance as the alternative, with the government taking steps to look after those who could not pay. This alternative would mean, however, that more and more people would be classed as "medically indigent"—eventually including those with incomes of $50 a week or more—because they could not afford the high fixed premiums of voluntary insurance schemes. "The result, I am convinced, would be to put the government so deep in the business of providing free medical care that we should never get out of it. Once the pattern was set, we should indeed be on the road to socialised medicine with a vengeance."

Medical Practices Committee

The London Local Medical Committee on Sept. 28 to inform the London Executive Council that it is opinion that the whole of London should be regarded open area.

Mr. A. J. Wright will deliver the Semon 1, Wimpole Street, W.1, on Thursday, Nov. 3, at 5 is to speak on Tonsillar Function.

Dr. Brock Chisholm, director-general of the World Organisation, has been paying a visit to Brazil. From he went on to Peru, and he is returning to Lake Success.

Copies of the catalogue of the Jenner bicentenary (*Lancet*, Oct. 1, p. 616) are obtainable from the University Press, who are publishing it on behalf Wellcome Historical Medical Museum.

The proceedings of the Family Planning Asso conference on infertility held in Exeter in Septemb year (*Lancet*, 1948, ii, 542) have been published. price 10s. 6*d*. each, are obtainable from the association Eccleston Square, London, S.W.1.

CORRIGENDUM: *Clues to the Ætiology of Graves's Di* In this lecture by Professor Means, printed in our is Sept. 24, the last sentence of the third paragraph und heading "adrenal cortex" (p. 547) should read: "If the administration of either adrenaline or adrenocortico hormone there is no fall in the eosinophil-count, the conc is that the cortex is incapable of being stimulated."

Appointments

BARRAN, G. F., B.A., M.D. Camb.: consultant chest physi King's Lynn and West Norfolk area.

JACKSON, M. I., M.R.C.S.: consultant chest physician, Newport East Monmouthshire area.

McILROY, W. E., M.B. Belf., D.P.M.: psychiatrist, Barming Hospital, Kent.

NELSON, I. D. M., M.B. Belf., D.P.H.: deputy M.O.H., Dewsbury.

RAFTERY, LILIAN, M.R.C.S., M.M.S.A., M.R.C.O.G.: asst. vi gynæcologist and obstetrician, King Edward VIII Ho Durban, Natal.

STEWART, R. H. M., M.D. Lpool: senior M.O., Manchester Regi Hospital Board.

WILLIAMS, A. H., M.D. Lpool, D.P.M.: psychiatrist, Barming He Hospital, Kent.

Colonial Service:

HARGREAVES, ANTHONY, M.A., M.B. Camb.: dermatolo Kenya.

NUNN, J. F., M.B. Birm.: M.O., Malaya.

Births, Marriages, and Deaths

BIRTHS

ANDERSON.—On Oct. 6, in London, the wife of Dr. T. B. Ande —a daughter.

BURNE.—On Oct. 6, at Sheffield, the wife of Dr. J. C. Burn daughter.

FAIRLIE-CLARKE.—On Oct. 3, at Greenham Common, Newb the wife of Mr. G. A. Fairlie-Clarke, F.R.C.S.—a daughter.

FURNIVAL.—The wife of Dr. J.T. Furnival—a son.

GOULD.—On Oct. 1, at Buxton, the wife of Dr. L. N. Gould—a

GRIFFITHS.—On Sept. 30, the wife of Dr. F. E. D. Griffiths—a

MACDONALD.—On Oct. 7, at Chesterfield, the wife of Dr. J

1 London, the wife of Dr. A. G. Pea

SHAPIRO.—On Oct. 2, at Didsbury, the wife of Dr. H. J. Shap a daughter.

MARRIAGES

BURNS-PRICE—THORP.—On Oct. Harry B

1, at Worthing, John Es ry York Moore.

, John Francis Nunn, M.

1, at Newport, Isle of W tty Bristow.

at Fetcham, Surrey, David Elspeth Mary Frith, M.B.

DEATHS.

FORD.—On Oct. 3, at Eastbourne, Frank Chubb Ford, M.B. D aged 82.

GREENWOOD.—On Oct. 5, in London, Major Greenwood, Lond., F.R.C.P., F.R.S., aged 69.

LANYON.—On Oct. 4, at Penzance, Edgar Temple Lanyon, M

C DEPARTMENT, WESTMINSTER HOSPITAL; ASSISTANT
IAN, MOORFIELDS, WESTMINSTER, AND CENTRAL EYE
AL: LATE PATERSON SCHOLAR, CARDIAC DEPARTMENT,
LONDON HOSPITAL

With illustrations on plate

nervous and cardiovascular systems are together urce of most of the troubles of old age. The old has a heart which deserves special attention, for survived the hazards so dangerous in the preceding ecades. Even so, most of the aged die from heart ons. I know of only one book in English which deals with the cardiology of old age—namely, Balfour's *Senile Heart* (1896)—but modern cardiological ms in the aged have been reviewed by Freedberg ewis (1944). Allbutt (1915) and Mackenzie (1923) written much of interest, and Sheldon (1948), in ey of more than 400 old people, has given details incidence of cardiac and other symptoms.

nitions.—It is first necessary to define some "Senility" is pathological old age, and "senes-" should be applied to the process of growing old. ontology" is the science of old age, and "geriatrics" treatment of diseases of old age. "Old age" is ficult to define as childhood, maturity, and middle The State has decided that it begins at 60 in women 5 in men, but we do not accept that as physiologists. ieve that 70 is correct for both sexes, if we take the gical limit of human life to be 100 years. True that many are older than their years. In fact, as ames Paget (1902) said, "we do not measure a man's by the earth's revolutions around the sun but by revolutions of his morbid processes." "There are s in the chronometry of life," he observed, "and small beginnings in early life they become con-tly more serious." Old age is a natural process should not have the stigma of morbidity attached to Yet certain pathological processes are so common they have been regarded by some as inseparable old age—e.g., arteriosclerosis.

NORMAL AGEING

arthin (1928) reminds us that ageing is an involu-ary process which is inherent in the organism, and s irrevocable and incapable of retardation to its mate end in biological death. Whatever power we have in inhibiting the ravages of disease we cannot, shall we be able to in future, prolong human life ond its biological limit, which, with few exceptions, s not extend beyond 100 years. This emphasises the tence of a normal old age, and Warthin goes on to the tissue changes during the involutionary period and pares them with those found in the human placenta, ich grows, matures, involutes, and is finally dis-ded as useless. Involution is characterised by atrophy tissues; the cells lose their power of division eneration is less, and supporting tissues atrophy. s process is found in every tissue of the body, of special interest to us are the changes in the rdiovascular system.

When a biological death takes place at an old age, the e energy of the organism is spent, and nothing can olong life. The candle of life, as it were, snuffs out. he heart is the prime mover in life, and a biological ath is a primary cardiac death. It is not easy to ecide in what cases a biological death has taken place and Warthin states that in his thirty-eight years' experience of morbid anatomy he could recall but 25 necropsies in which biological death could be presumed. His protracted study of the problem, however, is worth noting, for he regards arteriosclerosis as an essential feature of ageing, accepting that the degree of this varies much, and that very old people may have no arteriosclerosis demonstrable clinically. Korenchevsky (1949) concludes that the primary cause of physiological senescence in old age is still unknown.

A study of centenarians was carried out by Humphry (1889), and from them it was thought that the normal ageing processes could be deduced. The hearts examined showed atrophy in some and hypertrophy in others but rarely gross hypertrophy. Fatty accumulation about the heart was a constant finding. The great muscular arteries were often cartilaginous or ossified, but in one patient, aged 107, there was minimal atheroma in the aorta. Harvey (1635) examined the heart of old Parr, aged 152, and reported as follows:

> "The heart was large and thick and fibrous, and contained a considerable quantity of adhering fat, both in the circumference and over its septum. The blood in the heart, of a black colour, was dilute and scarcely coagulated; in the right ventricle alone some small clots were discovered."

Harvey, according to Thoms (1873), did not vouch for the age of old Parr but simply recorded what he found, and there are few centenarians whose age could be guaranteed after adequate search for errors in recording the age.

It is of some interest to note that investigations of previous generations show that the biological life span has not increased. More live to an old age than formerly but since man gave us records the age of the oldest people has been the same whatever the race or generation (Thoms 1873). There is thus some hope that the world will not become as overpopulated as some fear.

THE NORMAL HEART IN OLD AGE

Everyone is familiar with the appearance of the normal aged person and with the infinite variations described in published reports. The pulse-rate scarcely varies in the different age-groups. There is a reduction of exercise tolerance, but dyspnœa is not a feature of healthy old age if the physiological amount of exertion appropriate to the age is taken. The configuration of the chest tends to kyphosis from atrophy of vertebral discs, but here again it is not an invariable accompaniment of old age. A reduction in vital capacity is likewise not essential, but it has been shown that a substantial reduction usually occurs, due to kyphosis, to a high diaphragm, and to reduced elasticity of the lungs.

The heart may appear as normal at the age of 90 or even 100 as at that of 50. The apex-beat is usually more difficult to localise because of emphysema but it can be distinct. The heart sounds should be clear and unaccompanied by murmurs, though systolic murmurs are frequent and need have but little significance. Anatomically the aged heart is like the younger except for an excess of fat in the normal grooves and for opacity of the pericardium (fig. 1). Brown atrophy is often seen with reduction in striation. The heart weight is not materially altered but in relation to the total body-weight, which is usually lowered, it may be relatively heavy. Boyd (1861, cited by Humphry 1889) contrasted the heart weights of men and women aged 30–40 with those aged 80 or more, but they differed little, allowing for total body-weight, whereas the spleens and kidneys of the aged were half the weight of those of the young.

The heart chambers are not remarkable in the healthy old patient. The valves are sometimes sclerosed or even calcified. A slight degree of this can be regarded

---

The Goulstonian lectures of the Royal College of Physicians delivered on Jan. 11 and 13, 1949.

as normal; but, if the valves become incompetent or stenosed, we must certainly accept a pathological degree of change to have taken place. Yet so many works on "normals" include such cases. Though gross changes in the valves may be found in symptomless old age they are nevertheless to be regarded as pathological. The degree of change that can be allowed as normal is determined by the least amount found in the oldest of patients.

The aorta dilates, lengthens, unfolds, and becomes less elastic with age—so much so that on cardioscopy one has come to be able to tell the patient's biological age from the appearances of the aorta. The actual age in years is impossible thus to foretell. Patients may live despite gross changes, but that detracts not an iota from the fact that the changes are pathological. The great muscular arteries share the same fate. They become dilated, thickened, and tortuous, but only a slight degree is permissible in normal old age. The small muscular arteries, including the coronary vessels, show mostly intimal thickening, whereby the lumen is narrowed. This causes a reduction of blood-supply to the various organs, but since these are undergoing involution they need less oxygen, and a physiological state for old age persists. But, if atheromatous degeneration supervenes, we are dealing with a pathological process, however common it may be without the deleterious effects of ischæmia.

It is for the clinician, and later the morbid anatomist, to decide how far the pathological changes secondary to involution have altered function. Function does not run parallel with the pathology, as we all know, and there lies the need for clinical judgment based on all available evidence. "A man is as old as his arteries," says Cazali. Yes, but one of these may be diseased out of all proportion to the others, and we are all familiar with the small plaque of atheroma in a coronary vessel that has caused death, when all other vessels show but a trace of abnormality. Nevertheless it is our practice, and rightly so, to make use of group medicine in the management of the individual, realising as we do the narrow limits within which we can apply the general to the particular.

MATERIAL

I have specially studied 360 patients over the age of 70 (mostly during five non-consecutive years broken by Army service) at the Westminster Hospital, at the Moorfields, Westminster, and Central Eye Hospital, and in private practice. But I have naturally drawn much on the experience of earlier cases, of which I have records, at the London Hospital, both in the general wards and in the cardiac department.

The eye patients, 100 of them, were seen mostly as outpatients for assessment of their general condition, but apart from these the cases here analysed are representative of what a physician interested in cardiology may meet from day to day in medical and surgical wards and in practice. In this feature lies the interest of my personal series, for larger groups are to be found in special departments. The proportion of old patients among my records of all cases varied at different times from 2 to 10%.

TABLE I—AGE AND SEX OF PATIENTS

No. of cases	Whole group		Eye patients	
	Average age (years)	No. of patients over 80	Average age (years)	No. of patients over 80
Males 179 ..	74	15	74	5
Females 181 ..	73·5	19	72 8	7
Totals: 360	73·8	34 (*9·4%*)	73·3	12 (*12%*)

The age of my patients averaged 73·8, and it similar in males and females, both in the eye and in the total group. There were 34 patients over 80 (table I).

ÆTIOLOGICAL TYPES OF CARDIOVASCULAR DI IN THE AGED

Congenital.—Only 1 patient in my series had a genital anomaly—bicuspid aortic valve with imposed atheroma. Abbott (1936), in her analys 1000 necropsies on patients with congenital ca disease, records the following abnormalities in pat aged 70 or more:

	Age
Pericardial defects	78
Anomalous chordæ in left auricle	84
" " " aorta	76
Patent foramen ovale	70
Defect in interventricular septum	79
Supernumerary cusps of pulmonary valve	90
Coarctation of aorta (adult type)	93
Double aortic arch	87
Anomalies of pulmonary veins	86

Rheumatic.—Very few cases of unquestiona rheumatic valvular disease presenting as such sur to the age of 70, but overlying atherosclerosis is comm particularly in the ætiology of aortic stenosis. rheumatic lesions here predispose to degenera changes with atheroma, which are dealt with bel White and Bland (1941) described a patient, aged with rheumatic mitral stenosis.

Bacterial Endocarditis.—The subacute form is unkno after the age of 70, but the acute form may occur septicæmia. I have met no such case.

Syphilis.—There was no evidence of syphilitic hea disease in any of my patients. Few syphilitics survive the age of 70, but Jones and Bedford (1943) found seve patients aged over 70 with aortic incompetence a angina pectoris. None started angina after the age of but 28 of 103 started it between the ages of 60 and Syphilis should therefore not be discounted because mere old age. On the other hand, care should be ta not to diagnose syphilitic angina just because abnor pupils seem to indicate syphilis, for these pupill changes simulating Argyll Robertson pupils are of due to arteriosclerosis and rigidity of iridal vessels.

Thyrotoxicosis.—It is not rare to find aged patie with frank thyrotoxicosis, and very many more h auricular fibrillation with otherwise masked th toxicosis. Subtotal thyroidectomy was formerly successful in the treatment of these patients, but now have thiouracil for less suitable candidates operation. Auricular fibrillation occasionally per because arteriosclerosis coexists, but thyrotoxic does not favour atheroma, because of diminished bl cholesterol. Of my patients 7 had goitre. The only had exophthalmic ophthalmoplegia and paroxys tachycardia, possibly fibrillation. A woman, aged had auricular fibrillation with a ventricular rate of but she refused treatment and discharged her Another women, aged 75, had slight congestive he failure with normal rhythm but lived eight years lo on digitalis leaf gr. 1 b.d., which controlled the ta cardia to some extent. Another had thyroidectomy at age of 68, and at 74 she was still toxic but with failure and sinus arrhythmia. A woman, aged 78, survi thyroidectomy for an enormous goitre which showe evidence of toxic changes histologically and she was on discharge three weeks later. She was the only pat without hypertension, her blood-pressure being 12 Two others had toxic goitre, hypertension, and nor rhythm.

Myxœdema must be suspected, but it is rare, an have only 1 patient whose myxœdema began after age of 70. She responded at once to thyroid and remai well, with a blood-pressure of 150/95.

ic myocarditis with acute failure was common in lphonamide days in lobar pneumonia and in hopneumonia, and in patients treated late this lication is still seen. It is usually fatal; but, if it venes late in the illness, there is some hope of ery, particularly with the help of mercurial diuretics. not easy to recognise in the feeble aged especially, se peripheral failure so often coexists, and the veins may therefore not distend. Œdema in the l area need not be cardiac but it usually is. One patient recovered with the aid of digitalis, but was old-standing hypertension, which probably ibuted to failure precipitated by the pneumonia. must suspect too that a pulmonary embolus may be ause of bronchopneumonia, and cor pulmonale may t. Toxic myocarditis is in fact rare, and in cases agnosed death results more often from peripheral latory failure and cerebral ischæmia.

ronic cor pulmonale is rare in the aged, and I have ded only 1 case, in a man aged 70, who had had chitis for twenty-five years. The outflow tract of heart was enlarged. The rarity of this condition e aged is interesting, but it would be diagnosed often if hypertension were not so commonly istent.

ronchitis has an important aggravating action when heart is already diseased by hypertension or by nary sclerosis. The bronchitis may be perpetuated gravated by congestion from a failing left ventricle a auricular fibrillation. Bronchitis was a feature in rd of my patients.

enal Heart-disease.—Most, if not all. patients with ht's disease have died before reaching the age of and this fact has not been emphasised enough to date. ve no example of Bright's disease in the aged. The eys often showed ischæmic changes, macroscopically histologically, but only 1 of 8 cases revealed this great degree. A man, aged 70, was in failure with othorax following a coronary thrombosis. His od-urea level was 242 mg. per 100 ml., and he was ught to have chronic nephritis. At necropsy the neys were healthy, each weighing 8 oz. The heart ghed 19 oz. The prostate was healthy. It is important note that the urine had been concentrated, and al heart-disease need not have been suspected. The ed blood-urea level was of extrarenal origin. Albumin- i is not so common as might be expected from arterio- otic renal changes. It was present, though most n as a trace, in 34% of my patients, so many of om were hypertensive. The specific gravity of the he averaged 1·016, and in a third of the patients it s 1·018 or higher. These simple tests remain of great ue in the aged. In hypertensive old men the prostate o be blamed rather than chronic nephritis, if uræmic ptoms appear.

ARTERIOSCLEROSIS

I had thought that in old age it might be possible find some relationship between the blood-pressure d arteriosclerosis in the various clinically accessible eries, in the limbs, retinæ. and heart; for at the age 70 the processes might be considered established. at no such relationship could be found on careful utiny of the figures.

The limb vessels appeared normal in half the cases. oth upper and lower limb vessels were abnormal in quarter, and the lower limb vessels in a third. There as no significant difference between the hypertensive nd non-hypertensive groups. Nor did a high diastolic tion show a preponderance of vessel changes in the mbs. Gross rough thickening of the brachial arteries n non-hypertensives was usually associated with a poor eneral condition. In these old people the condition of the limb vessels bore no relationship to the retinopathy, which was almost always hypertensive, or to coronary disease as evinced by coronary pain.

Intermittent claudication as usually described was found in 4 of 360 cases, and nutritional damage in extremities in 2 others. But, as Mackenzie (1923) pointed out, the classical symptoms are not always present when the same process, defective blood-supply, is at work; pain in the thighs or back or, rarely, in the upper limbs may have the same significance. Moreover, limitation of activity by shortness of breath may protect the patient from intermittent claudication proper.

Kinked carotid was found in 4 women over the age of 70 with blood-pressures varying from 130/90 to 260/170. Parkinson et al. (1939) described the kinked carotid that simulates aneurysm, and their paper shows a radiogram of a woman, aged 79, with the characteristic shadow at the apex of the right lung.

BLOOD-PRESSURE

The idea that the blood-pressure should rise with ageing, and that at the age of 70 it should be 170 mm. Hg, has created two sets of unhappy old people: those who are said to have too low a blood-pressure, and those said to have too high a one. Now, it is common medical experience that two men aged 70 may have a blood-pressure as low as 110/70 and as high as 230/120 with the same expectation of life as a third man with a blood-pressure of 170/90. Among the most robust aged persons are the hypertensives, and the dreaded cerebral hæmorrhage is extremely rare after the age of 70.

There is no normal for old age, but I think it is best to regard the blood-pressure as abnormal, whatever the age, if it exceeds 160/100. This does not mean that treatment need be instituted if a higher figure is obtained. The organs may go on living without producing symptoms, despite pathological phenomena, and this applies specially to the old.

The average blood-pressure in patients first seen at the age of 70 or more was 188/102. Raised tension (over 160/100) was found in 67·4%, normal tension in 29·9%, and "low" tension (115/80) in 2·7%. These figures closely simulate those found by Howell (1944) in Chelsea pensioners. Of the eye patients 88·8% were in the hypertensive group, and none in the lowest tension group. The average for the eye patients was 211/100.

An analysis of patients over the age of 80 (22 cases) showed an average of 193/105, which does not differ much from that of the whole group. The averages for the separate sexes in patients aged over 80 was 200/103 for males and 189/105 for females, a similarity which is important in view of the lesser tolerance of hypertension by middle-aged men. One old man of 80 had a blood-pressure of 270/160.

The eye patients with hypertension were specially interesting in that, apart from defective vision, they were generally in good health. Though the heart was often enlarged, congestive failure was rare. A very few had paroxysmal dyspnœa, but the vast majority had no dyspnœa at all. Dizziness was common but seldom disabling. Angina pectoris was present in a few, and 1 developed coronary thrombosis while under observation. A silent gap was noted on sphygmomanometry in 3 cases, an incidence expected in hypertensives at other ages. Gallop rhythm, canter rhythm, and pulsus alternans were noted occasionally. Systolic murmurs were common at the apex, base, or both. The arterial tree in these eye patients was often remarkably normal, and the predominant abnormal finding was thickened tortuous but resilient vessels. Pulsation in the vessels of the feet was normal in the great majority, and absence of pulsation was more often due to difficulty in palpation through thickened tissues about the ankle and tarsus *than to obliterated arteries. This group contrasts with* non-hypertensive patients, in whom arteriosclerosis is more threatening to the extremities.

As regards the prognosis of hypertension in the aged, a few examples may be mentioned of patients who have survived gross hypertension for several years.

A woman, aged 73, when first seen had a blood-pressure of 270/140 and gallop rhythm; she was still fairly well five years later.

Another woman, whose blood-pressure was 270/190, with thick tortuous arteries in 1938 at the age of 73, recovered from an attack of congestive failure ten years later when, aged 83. Her blood-pressure was then 175/95, and her heart was only a little enlarged as a whole.

Another woman, aged 75 in 1939, had a large pulse pressure, 200/70, and a dilated aorta (non-luetic) but no aortic diastolic murmur, and she was still alive eight years later at the age of 83.

I cannot agree with Thewlis (1946) that a blood-pressure of 110/70 is ideal in old age.

RELATIONSHIP BETWEEN ARTERIOSCLEROSIS AND HYPERTENSION IN OLD AGE

There are four fundamental groups which at least facilitate discussion, even if in practice it is difficult to place many borderland patients within them.

(1) *Hyperpiesia of Allbutt* (1915).—Here the condition is believed to be one of primary hypertension beginning in earlier decades, from 45 to 60, with an average duration of 10–15 years. Allbutt thought, however, that this type could rarely begin after the age of 70, and this view is supported in my series. Cardiovascular hypertrophy is the essential feature.

(2) *Decrescent Arteriosclerosis of Allbutt* (1915).—The term decrescent is preferred to involutionary because it is not physiological. *Here the clinically important changes mainly* affect the intima. The age-incidence is higher than in the first group, beginning at the age of 55, and the process is of indefinite duration. If this kind of arteriosclerosis does not develop in earlier life it will not come to much later.

(3) *Hyperpiesis Secondary to Arteriosclerosis.*—Many of our old patients are in this group, though clinically either hypertension or arteriosclerosis appears to dominate. The changes mainly affect the intima of the muscular arteries and the elastic constituents of the great elastic arteries, such as the aorta. Cardiovascular hypertrophy is slow in developing and is responsible for the state of hypertension without enlargement of the heart so commonly found in the elderly. There are two subtypes: (*a*) with large pulse pressure, when the great vessels are dilated; and (*b*) with normal pulse pressure, when the smaller vessels suffer most.

(4) *Arteriosclerosis Secondary to Hyperpicsia.*—The arteries are clinically tortuous and thick but often still resilient because hypertrophy is dominant.

With these groups in mind, a full history and clinical, radiological, and electrocardiographic investigation and a long follow-up will enable us to put most of our elderly patients into one of them, but some will still defy classification until necropsy.

CORONARY DISEASE

There were 42 (10·7%) patients with clinical coronary disease, 23 males and 19 females, of equal average age 74; 2 males were aged 80 and a female 84. Two-thirds were hypertensive, mostly females, as in younger age-groups.

Coronary infarction occurred in 20 patients, 12 male and 8 females. It proved fatal in 3 only. Since anastomoses are virtually absent in the old, this high rate of recovery is notable. The incidence of anterior and posterior infarction was equal. The myocardial infarction was without pain in 2 cases, and 1 patient presented with a faint. Cookson (1942) comments on this feature; 5 of his patients aged 70 or more had syncope at the onset. Palmer (1937) found that survival to death or last observation after coronary thrombosis in 4 patients aged 70 or more was 2·93 years.

Abdominal angina was a striking feature in a aged 80, who had survived a coronary thromb years previously. Another man, aged 72, with clinical coronary disease, had several attacks of vi abdominal pain due presumably to slight dissection extended clotting in his arteriosclerotic abdom aneurysm (fig. 2), which could be felt and seen w radiography.

A man, aged 79, reported that after several typical angina he was now free and felt very well. *pain of angina of effort retains in the old* the features as in the younger group but is more accompanied by non-coronary left submammary of postural origin from kyphoscoliosis. Trinitrin angina of effort just as readily in the old as in the y Sheldon (1948) states that only 3 of 11 patients angina had sought medical advice before his s of symptoms in old people.

Mackenzie (1923) recorded many examples of an pectoris in patients over the age of 70. His case 36 a man whose first pain occurred at *the age of 74.* survived through years of frequent pain up to fourt attacks a day, and finally the angina virtually left at the age of 82. Case 40, a man aged 76 when his attack occurred, died eight years later at the age of These are examples of longevity despite angina. Ca (1946) found in his patients that 19% of females a 12·1% of males were over the age of 70.

PULMONARY EMBOLISM

Pulmonary embolism occurred in 6 patients, 2 fem and 4 males. Three bedridden patients died from mas pulmonary infarction from emboli detached fr *spontaneous pelvic-vein thrombosis.* Of the non-fa cases, 1 had auricular fibrillation, and the remain 2 were postoperative, after eye operations.

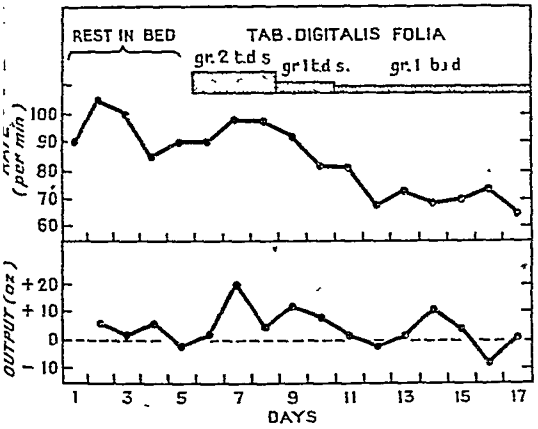
AORTIC VALVULAR DISEASE WITH INCOMPETENC

This was found in 6 cases, 2 females and 4 ma All but one had a raised systolic pressure average 1 and the average diastolic pressure was 83. There remain a clear diastolic point in each case. The Wasserma reaction was negative in all cases. Stenosis was prominent in any of these, but in other patients p senting with a systolic murmur at the apex and ao area some stenosis was probably present though n had the classical signs. As previously mentioned, und lying rheumatic disease is a *determining* factor in localisation of atheroma on the aortic valve.

HEART ENLARGEMENT AND AUSCULTATORY SIGNS

Apart from aortic valvular disease (dealt with in foregoing section) the heart was enlarged in 38·1% patients. Most were confirmed radiologically. A fe not included, were thought to have enlargement clinicall but no enlargement was found radiologically, wherea a few of those included had radiological enlargemen not detected clinically. This contrasts with the finding of Fox et al. (1948), who report 52·6% of 300 amb lant males over the age of 60 as having radiologic enlargement of the heart.

Well-defined murmurs at the apex or base, or both were found in 22·6%, and murmurs were found muc less often in the normal-sized hearts (15·4%) than in th large hearts (34·3%)—i.e., half as often. But large heart are therefore often unaccompanied by murmurs, though one adds triple rhythm, which so often takes the place o murmurs, the percentage of abnormal auscultatory sign in enlarged hearts rises to 48·6%. Yet it should b remembered that auscultatory signs are difficult t appreciate in the old, and this percentage still appear *too low.*



-Effect of rest and digitalis in heart-failure with auricular fibrillation in man aged 72 with blood-pressure 150/90.

CONGESTIVE HEART-FAILURE

ıgestion was found in 46 of 360 cases (12·7%). compares with 22·1% of Willius's (1931) series of ıatients, aged 75 or more, who came for electro- ıgraphy. Normal rhythm was present in 30 of my (65·2%), fibrillation in 13, flutter in 2, and heart- in the other, these arrhythmias accounting for ó. Coronary infarction was recent in 3 and past ıthers. Three further patients had angina of effort. t from these coronary cases, 60% were hypertensives, most non-hypertensives were fibrillating. There 1 chronic cor pulmonale and 1 toxic myocarditis hypertension, and 2 failed after prostatectomy. lema was usually present, and hydrothorax occurred 17 4%). Total failure was moderate or great in over Twelve (26%) died while under observation. There several examples of paroxysmal dyspnœa among ıatients with congestive failure, and 3 not included had such attacks without showing frank congestion e time of examination. A major difficulty arose stinguishing cardiac from bronchial asthma; in I believe that, in the aged especially, they may times coincide, and it is a fine judgment to decide is dominant. Yet this is important from the of view of treatment, and, when in doubt, morphine and atropine gr. 1/75 subcutaneously, and if possible n, should be the first treatment, followed by therapy ding to indications as the attack is observed er. Strophanthin (with due regard to previous lis therapy), nikethamide, aminophylline, or aline may then find its proper place.

e differential diagnosis of congestive heart-failure be difficult in the aged. Œdema is not always ac; it may be due to varicose veins, anæmia, utrition, obesity, cirrhosis of the liver, or pelvic ur. "Shelter" œdema was common during the

TREATMENT OF CONGESTIVE HEART-FAILURE

gitalis is commonly thought to be less effective e aged than in the younger patients, and this was mpression gained by Gavey and Parkinson (1939) studying digitalis in heart-failure with normal ım. Yet among those aged 65–70 no fewer than 9 patients responded, and 2 of them well. Older nts may still benefit in a striking manner irre- ive of rhythm, and a greater number benefit over periods, especially in preventing paroxysmal nœa. As Luten (1936) says, it is not age but the type art-disease that is the determining factor in response igitalis.

e heart-rate in the aged becomes very important ilure. One is so used to seeing ambulant old folk with slow fibrillation that there is a tendency to overlook the brisk rise often found when failure sets in. Digitalis may control this rate and promote diuresis (fig. 3). The standard dose of digitalis leaf, gr. 2 t.d.s. for 5–8 days, may be used, but it is wise not to use heavier dosage except in acute failure, for the natural tendency to arrhythmias in the aged heart may be enhanced by digitalis with fatal results. In slight cases gr. 1 t.d.s. is sufficient. When failure has developed, a maintenance dose of digitalis is almost always indicated, and this varies much in the aged person, from gr. 1/2 b.d. to gr. 1 b.d. Whereas the usual signs of digitalis toxæmia obtain in the old—anorexia, nausea, vomiting, and coupling—yet a feeling of general weakness and exhaustion without those signs and unaccompanied by more dyspnœa occur often enough to be respected; and proof of this digitalis effect is found in reappearance of well-being after two or three days without digitalis. It is important that the patient shall not lose faith in digitalis, for it is likely to be required more, not less, as the illness advances, and care in its administration will be fully repaid. I have not found that a change of preparation improves tolerance to digitalis; it is a matter of adjusting the dose, and a small one may be effective. In this respect it is to be remembered that many aged patients with failure have lost much flesh and are of a small build. In failure with normal rhythm the rate may be slowed, just as in the younger group, but improvement does take place independently of the heart-rate. Patients with normal rhythm obtain benefit as often as the fibrillators—about two-thirds.

Auricular fibrillation was present in 12 other patients without congestion. If the ventricular rate tended to be rapid, over 80 at rest, digitalis was given in small doses —e.g., gr. 1 of the leaf b.i.d. or daily—in the belief that release of the heart-rate occasioned by ordinary stresses and strains of daily routine would not so easily occur and so failure would be postponed. Quinidine is not precluded by age. Its chief indication is in fibrillation caused by a transient agent, such as anæsthesia, but spontaneous return to normal rhythm is common.

The mercurial diuretics are as powerful in the aged as in the young, and the partnership with digitalis is indicated (fig. 4). Care is required in old men with

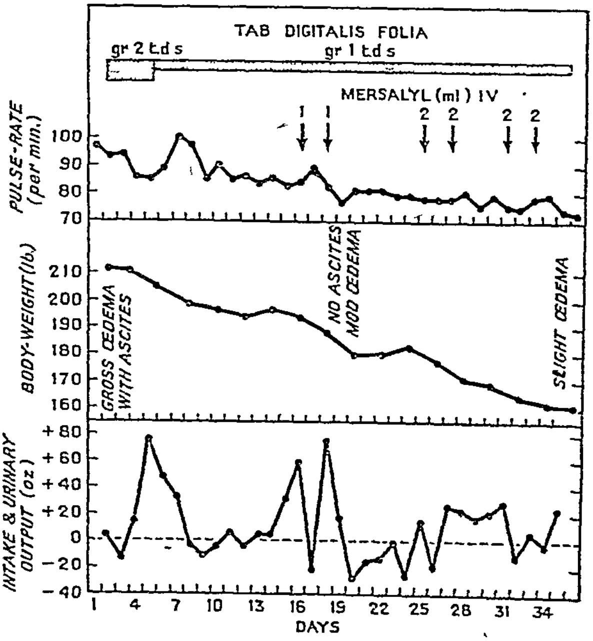


Fig. 4—Effect of digitalis and mercurial diuretics in hypertensive heart-failure with normal rhythm in man aged 77 with blood-pressure 210/145.

through thickened tissues about the ankle and tarsus than to obliterated arteries. This group contrasts with non-hypertensive patients, in whom arteriosclerosis is more threatening to the extremities.

As regards the prognosis of hypertension in the aged, a few examples may be mentioned of patients who have survived gross hypertension for several years.

A woman, aged 73, when first seen had a blood-pressure of 270/140 and gallop rhythm; she was still fairly well five years later.

Another woman, whose blood-pressure was 270/100, with thick tortuous arteries in 1938 at the age of 73, recovered from an attack of congestive failure ten years later when, aged 83. Her blood-pressure was then 175/95, and her heart was only a little enlarged as a whole.

Another woman, aged 75 in 1939, had a large pulse pressure, 200/70, and a dilated aorta (non-luetic) but no aortic diastolic murmur, and she was still alive eight years later at the age of 83.

I cannot agree with Thewlis (1946) that a blood-pressure of 110/70 is ideal in old age.

RELATIONSHIP BETWEEN ARTERIOSCLEROSIS AND HYPERTENSION IN OLD AGE

There are four fundamental groups which at least facilitate discussion, even if in practice it is difficult to place many borderland patients within them.

(1) *Hyperpiesia of Allbutt* (1915).—Here the condition is believed to be one of primary hypertension beginning in earlier decades, from 45 to 60, with an average duration of 10–15 years. Strophanthin (with due regard to previous gitalis therapy), nikethamide, aminophylline, or renaline may then find its proper place.

The differential diagnosis of congestive heart-failure ay be difficult in the aged. Œdema is not always rdiac; it may be due to varicose veins, anæmia, alnutrition, obesity, cirrhosis of the liver, or pelvic mour. "Shelter" œdema was common during the ar.

TREATMENT OF CONGESTIVE HEART-FAILURE

Digitalis is commonly thought to be less effective the aged than in the younger patients, and this was he impression gained by Gavey and Parkinson (1939) hen studying digitalis in heart-failure with normal hythm. Yet among those aged 65–70 no fewer than of 9 patients responded, and 2 of them well. Older patients may still benefit in a striking manner irrespective of rhythm, and a greater number benefit over long periods, especially in preventing paroxysmal dyspnœa. As Luten (1936) says, it is not age but the type of heart-disease that is the determining factor in response to digitalis.

The heart-rate in the aged becomes very important in failure. One is so used to seeing ambulant old folk with slow fibrillation that there is a tendency to overlook the brisk rise often found when failure sets in. Digitalis may control this rate and promote diuresis (fig. 3). The standard dose of digitalis leaf, gr. 2 t.d.s. for 5–8 days, may be used, but it is wise not to use heavier dosage except in acute failure, for the natural tendency to arrhythmias in the aged heart may be enhanced by digitalis with fatal results. In slight cases gr. 1 t.d.s. is sufficient. When failure has developed, a maintenance dose of digitalis is almost always indicated, and this varies much in the aged person, from gr. $^{1}/_{2}$ b.d. to gr. 1 b.d. Whereas the usual signs of digitalis toxæmia obtain in the old—anorexia, nausea, vomiting, and coupling—yet a feeling of general weakness and exhaustion without those signs and unaccompanied by more dyspnœa occur often enough to be respected; and proof of this digitalis effect is found in reappearance of well-being after two or three days without digitalis. It is important that the patient shall not lose faith in digitalis, for it is likely to be required more, not less, as the illness advances, and care in its administration will be fully repaid. I have not found that a change of preparation improves tolerance to digitalis; it is a matter of adjusting the dose, and a small one may be effective. In this respect it is to be remembered that many aged patients with failure have lost much flesh and are of a small build. In failure with normal rhythm the rate may be slowed, just as in the younger group, but improvement does take place independently of the heart-rate. Patients with normal rhythm obtain benefit as often as the fibrillators—about two-thirds.

Auricular fibrillation was present in 12 other patients without congestion. If the ventricular rate tended to be rapid, over 80 at rest, digitalis was given in small doses—e.g., gr. 1 of the leaf b.i.d. or daily—in the belief that release of the heart-rate occasioned by ordinary stresses and strains of daily routine would not so easily occur and so failure would be postponed. Quinidine is not precluded by age. Its chief indication is in fibrillation caused by a transient agent, such as anæsthesia, but spontaneous return to normal rhythm is common.

The mercurial diuretics are as powerful in the aged as in the young, and the partnership with digitalis is indicated (fig. 4). Care is required in old men with

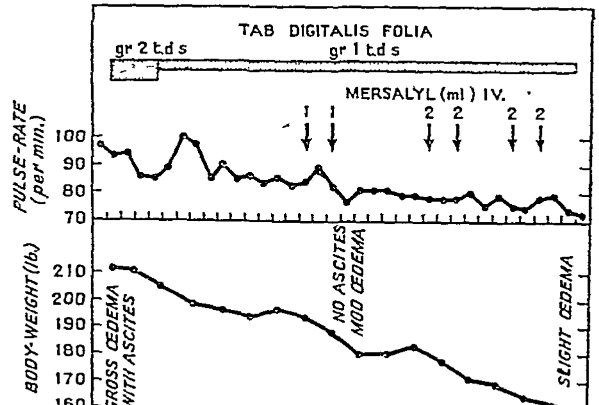

Fig. 4—Effect of digitalis and mercurial diuretics in hypertensive heart-failure with normal rhythm in man aged 77 with blood-pressure 210/145.

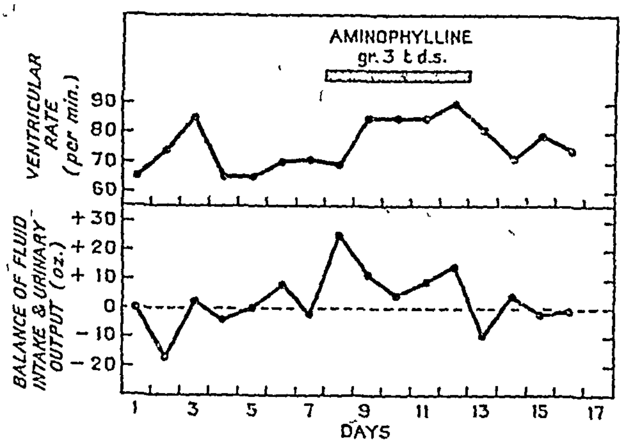

Fig. 5—Effect of aminophylline in hypertensive heart-failure with auricular fibrillation in woman aged 70 with blood-pressure 190/100.

enlarged prostates, for retention of urine may be precipitated by overdistension of the bladder.

Aminophylline by mouth has a place in treatment and may give a rest from injections of mercurials in slight cases (fig. 5) but it is not suitable for continued use, owing to gastro-intestinal disturbances. Aminophylline intravenously is specially indicated in the treatment of Cheyne-Stokes breathing, which is so common in the old, with failure, for abolition of the rhythm may greatly relieve the heart.

Sometimes failure becomes "irreducible." The patient remains in a state of chronic failure with œdema, despite digitalis and mercurials. The picture of the old man confined day and night to his grandfather's chair is familiar though much less common than formerly. In these patients Southey's tubes or multiple incisions may give great relief, and a waterproof plastic pillowcase is a convenient receiver for œdema fluid.

The general treatment of heart-failure with diet, restriction of fluids and of salt, is the same as in younger people, but rest can be overdone, and careful ambulation after at most six weeks may relieve œdema by reducing stasis. Hypnotics of choice are chloral gr. 20 and bromides gr. 20 together, morphine, or Dover's powder. Barbiturates are not well borne and tend to cause mental confusion if used often, but isolated doses of phenobarbitone or 'Sodium Amytal' may be useful. When congestion has cleared, odd days in bed may help a great deal in forestalling a relapse, and an occasional mercurial diuretic in addition to continuous digitalis therapy may prevent cardiac asthma. Optimistic handling is important. Vitamin deficiency must be excluded, for many old people find difficulty in obtaining sufficient food.

THE ELECTROCARDIOGRAM IN OLD AGE

Does the electrocardiogram of normal old age differ from that in younger persons? It is not surprising that we should have difficulty in replying to this we are continually discounting more and more abnormalities in the young. The range of the electrocardiograms of healthy young men to the likelihood of the aged electrocardiogram difficult to interpret as regards pathological I believe that the same criteria of normality applied to the old, but that some features, such axis-deviation, should be recognised as having prognostic significance. The same applies to the T A T I inversion in a man aged 70 is not so *prognostically as in a man aged 50, for the* the former are naturally less than on the latter, at both ages ischæmia of part of the myocardium be responsible. It is often found in healthy old but a normal electrocardiogram in every way rarer in an aged person than is the incidence of old age. A normal electrocardiogram by the young is never pathological for the old, just children a normal right pectoral lead is not pathol because so many children have an inverted T in lead. This reference to children, however, make hesitate to carry too far the idea that an electroc gram in an aged person should not deviate fro accepted normal for young adults. Just as growth alter the average pattern of the electrocardiogra may old age do so in devolution. Yet, as co disease is in the differential diagnosis from n

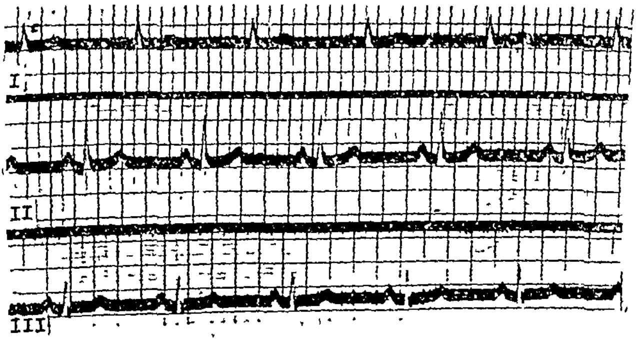

Fig. 6—Normal electrocardiogram in man aged 80.

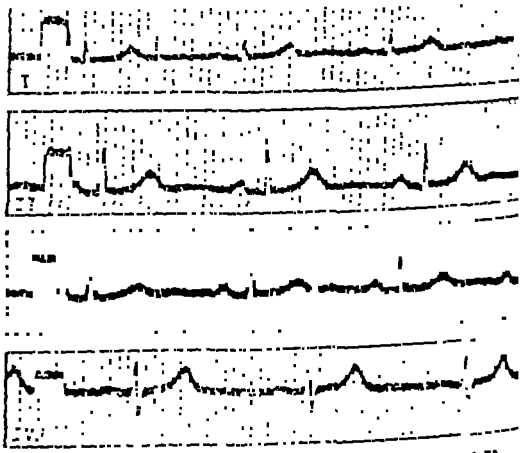

Fig. 7—Normal electrocardiogram in man aged 70.

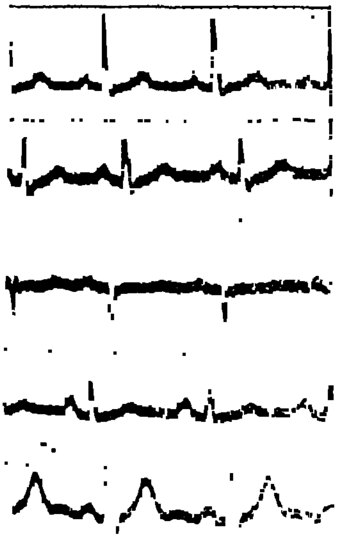
I feel it is correct not to accept readily as physiol for old age any deviation from the so-called "nor Fortunately we now have the help of chest lea regards left axis-deviation and coronary changes; so far as the standard leads go, we should rega pathological deviations from *the criteria* appli electrocardiograms of young persons, even thoug may take no action based thereon.

Analyses of the electrocardiographic finding healthy old folk show wide discrepancies, be patients studied on the ground that they were n revealed in a substantial proportion such ob abnormalities as auricular fibrillation, bundle-b block, hypertension, and cardiac enlargement. centages of "normal" electrocardiograms vari follows: 15% in ambulant males and females ove age of 70 (Eliaser and Kondo 1941); 33% in amb males and females aged 60 or more (Fox et al. 1 51% in ambulant males aged 60 or more (Fox 1948); and 74% in 100 males and females over th of 70 (Levitt 1939). This is clearly unsatisfac and, until a better correlation between clinical, ele cardiographic, and pathological material is avail *it is practical to use the same criteria* as in youth



—Normal electrocardiogram in man
74, showing effect of inspiration on
III.

ard the electrocardiogram as of less diagnostic rognostic importance in the aged than in the . The tendency is to rely too much on minor changes in the electrocardiogram, thus causing unnecessary invalidism. If we recall that gross disease of the heart, such as angina, may sometimes reveal no electrocardiographic changes, even after exercise, we shall return more humbly to the fundamental anamnesis in all cases.

If we cannot define absolutely a normal electrocardiogram for old age we can at least profit by studying the tracings in our atients who come to us for advice, and so reach ctical if not precise scientific conclusion. To this end se 200 consecutive patients, including 75 of my own, 70 or more, for analysis of their first electrocardio- s (table II). All these patients were submitted to ocardiography because it seemed indicated clinically. diagnoses therefore include all kinds of heart-disease in the aged. It will be seen that several rmalities are no commoner than in the so-called rmal" series cited above. The patients were aged , average 74; 21 were over 80.

ythm.—Normal rhythm (figs. 6–8) was present in %, with an average rate of 77 per minute, and all rhythms made up 82% of the total. *Sinus arrhyth-* was specially prominent in 1 patient, with a rate ing from 35 to 75 per minute: she complained only casional faintness. *Sinus bradycardia* was especially ounced in 2 patients, with rates of 38 and 32 per te (fig. 9). Both of these had attacks of loss of ciousness which simulated Adams-Stokes seizures were less abrupt in onset and offset and lasted longer. *illation* of the auricles accounted for 14·5%, with average ventricular rate of 95, higher than is com- ly thought to occur in old age. Only half showed te under 100. *Flutter* (fig. 10) was rare (0·5%); insonian tremor, so common in the old, may occa- ally simulate flutter, but lead III, not lead II, shows added waves (fig. 11); and *paroxysmal tachycardia*, uricular and 1 ventricular, was found in 2 cases h severe cardiac infarction.

rolongation of P–R Interval.—This was prolonged ond 0 2 sec. in only 11·5%. Apart from the non- us rhythms the percentage rises to 14%, still fewer n expected. In 3 cases the P–R interval was very ch prolonged (to almost 0·4 sec.), yet there were no pped beats.

Heart-block.—Complete heart-block was found in 2%. e incidence of *bundle-branch block* was 5%, less an that found by Eliaser and Kondo (1941)—12% healthy aged persons. Right bundle-branch block, wever, was not found in his series, and this abnormality undoubtedly has the more serious significance. The incidence of right and left bundle-branch block was equal in my series. All conduction defects, excluding minor abnormalities of the Q R S, amounted to 18·5%. Q I was prominent in 25·5% of cases, which is much higher than in "normal" series.

T-wave Changes.—In 39% there was an abnormal T I, and T III was alone abnormal in 21%. It is notable that in this series T was upright without R–T deviation in the three limb leads in 23·5%, indicating once more that heart-disease may often not be manifest electrocardiographically. The T waves and R–T segments are not further analysed, for they include changes due to coronary infarction and digitalis. The chest leads CR 1, 4, and 7 were tested in 40 patients, and the T wave in one of these groups was abnormal in 30%. T CR I was negative in 2 cases when the limb leads were normal, except for T III negative in 1 case; otherwise the chest leads did not reveal anything not suspected from the limb leads.

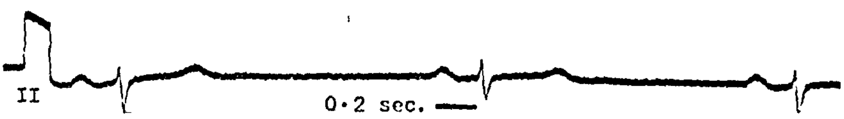

Fig. 9—Sinus bradycardia (32) in man aged 78, showing P–R greater than 0·2 sec.

U Wave.—This was present in 15% of cases in the standard limb leads, mostly in lead III. U IV or CRA was present in 36 cases in which the limb leads did not reveal it, and of these 7 were negative. All the latter patients with U negative showed gross disease; recent coronary infarction, heart-block, and great left ventricular hypertrophy. But a negative U was never the sole abnormality in the electrocardiogram.

Voltage.—Much has been written of a diminished voltage (fig. 12) being characteristic of old age, but it was found in only 5·5% of my series, and the voltage was considered low more liberally than the standard of 5 mm. set by the American Heart Association. The voltage in lead I was sometimes relatively low, as expected from the presence of emphysema. The high-voltage cases were usually hypertensive with enlarged left ventricles, but high voltage was not a common feature, even in the hypertensive group.

Axis-deviation.—As many as 71% showed left axis-deviation (figs. 13–16). A raised diaphragm accounted for some, since deep inspiration removed the axis-deviation in 14 of 35 of these patients in whom it was tried. This is not an infallible test, for occasionally a grossly hypertensive electrocardiogram with T I change may show loss of left axis-deviation in the limb leads on deep inspiration. Fig. 16 shows slowly progressive hypertensive changes in an old man. Only 3·5% of patients had right axis-deviation, and of those 7 patients 3 had auricular fibrillation, 1 auricular flutter, and 3 bundle-branch block. A quarter of the patients had no axis-deviation, and perhaps more would show a left one were it not for the influence of the common auricular fibrillation and emphysema. Yet one should not regard left axis-deviation as normal unless it is easily removed by inspiration and the chest leads reveal no corresponding abnormality.

Extrasystoles.—Many have regarded the occurrence of extrasystoles as of no greater significance at the age of 80 than at that of 20. Some have said that they produce fewer symptoms in old age (Eliaser and Kondo 1941). But caution is required, for despite reassurance of the patient they may still cause faintness and discomfort; and, if they appear in an elderly person who was known not to have them before, a careful history and examination may reveal the cause—e.g., a recent silent coronary thrombosis. If they are numerous, something is probably wrong, but other evidence will be found if sought. In doubtful circumstances a few weeks' observation may be better than dismissal with only. *Nevertheless most* be reassured when the sole finding. In 25·5% series extrasystoles were in a third of these they 3 per half-minute. extrasystoles were twice as common as

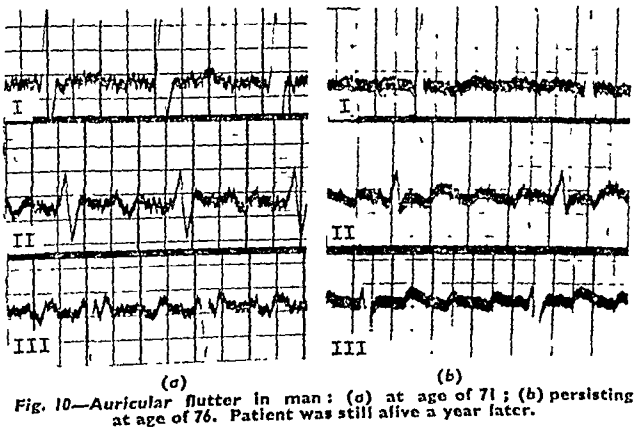

Fig. 10—Auricular flutter in man: (a) at age of 71; (b) persisting at age of 76. Patient was still alive a year later.

Conclusion.—I think all will agree that the feature is that so many aged folk have an cardiogram which deviates but little from the normal for young adults, when heart-disease is suspected. On the other hand, abnormalities electrocardiogram which do not depart gross normal—e.g., a prolonged P–R interval, and flattening—do not have the same prognostic as in the younger groups, even though they indicate the same nature of process at ischæmic fibrosis in the myocardium. Such cardiographic changes are compatible with a " *old age.*

RADIOLOGY OF THE SENILE HEART

Analysis of the radiological appearances of th in old people reveals variety of configuration. scoliosis is very common and is found in about cases. It i times gross diaphragm raised, sor with asymm a fifth c cases. Thi the heart an it a transve The diaphr low in the propor Considera cursion diaphrag remain in and its imp in the est of heart size shown in and 18. Calci of the costa lages is not its absence, except occasionally in the first rib radiological finding is borne out by necropsy, costal cartilages are cut with ease, as noted by (1635) in the case of old Parr and by H (1889).

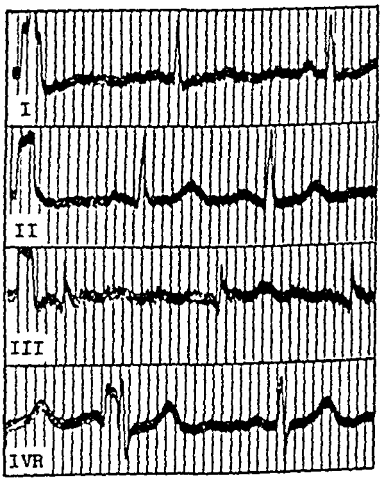

Fig. 11—Parkinsonian tremor simulating flutter in woman aged 70.

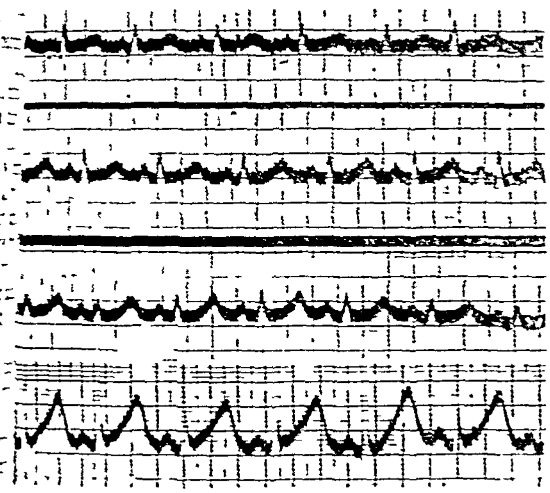
The heart and aorta may appear the same young persons, but this is the exception (fig. is by such standards that we should judge bi age. The pulsatile excursion of the heart d decrease with age. The aorta is usually unfol dilated to a variable degree (fig. 19), which se be independent of the height of the blood-p It is common to find a large heart in hyper with a minimal degree of unfolding and, on th hand, gross unfolding in non-hypertensives. tensives without cardiac enlargement may show much unfolding or none (fig. 20). A doubl knob, one within the other, is occasionally seen Kyphosis allows a good view of the unfolded a the left oblique position, in which we may also apex of the heart tilted upwards by a rigid u aorta (fig. 22). Ruffin et al. (1941) described condition termed by them senile ectasia of the There was local dilatation in the ascending aor arteriosclerotic. They described 3 cases, 1 with r *The average age was 71.* This is perhaps the only

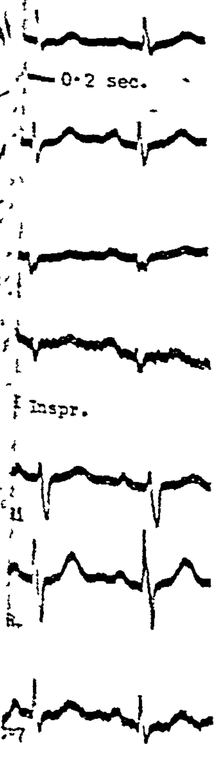


2—Low-voltage curve in electrocardiogram of man aged 71.

vascular condition confined to old age. I have ample of this or of arteriosclerotic aneurysm of oracic aorta, but 4 of my patients had abdominal osclerotic aneurysms (fig. 2). I have not seen hilitic aneurysm in a patient over the age of 70, xamples may occur.

ar congestion is valuable evidence of heart-failure 3). In emphysema the hilar root shadows are well and the right pulmonary artery stands out in the oblique position, though the main stem may not be ment in this position or in the postero-anterior. sionally the conus of the right ventricle humps the order of an otherwise normal heart, as in fig. 24. tal enlargement is characteristic of the fibrillators of long standing (fig. 25).

Unfortunately we cannot judge the thickness of the ventricles except by their outward shape, and angiocardiography has disappointed us in this; hence we still conveniently speak of enlargement. The aged heart does not often attain to great size (fig. 26 shows the largest in the series), and radiological help in deciding whether or not asthma is cardiac is not so often forthcoming as in younger persons. Yet at necropsy the cardiac muscle may be thicker than expected radiologically.



13—Left axis-deviation persisting with inspiration (T up all leads) in man aged 75 with blood-pressure 15: 90.

RISK OF OPERATION IN CARDIAC CASES

I have studied, immediately before or after operation, 51 aged patients, many of them in consultation because their cases were not straightforward. These included every grade of operation. 9 died, all of them after major operations, such as prostatectomy, excision of breast, and laparotomy for various carcinomas. Two emergencies, one a gangrenous appendix and the other a perforated gastric ulcer, were included.

It is difficult to apportion the part played by a failing heart in these fatal cases. In emergencies the risk of a faulty heart must be taken. A male, aged 76, with a gangrenous appendix, developed flutter at operation which was otherwise well borne, and paralytic ileus determined death on the eighth day. Digitalis and quinidine did not help, but congestive failure appeared only during the last two days. The other emergency case was a woman, aged 70, in whom auricular fibrillation supervened some days after operation which was well tolerated, but she died of heart-failure with a high ventricular rate uncontrolled by digitalis. Possibly an embolus was the reason, but permission for a necropsy was not obtained.

Both these patients illustrate how the heart may contribute to a fatal postoperative outcome though the operation itself was well borne. Arrhythmias are particularly common when there is toxæmia from peritonitis, as in the first case.

Of 7 fatal cases operated on deliberately, in only 1 could it be said that a better appreciation of the heart condition might perhaps have saved life by avoiding operation, however desirable it was as proper treatment for the local lesion. This condition arose in a woman, aged 77, with a blood-pressure of 160/110, who had a radical mastectomy and died on the eighth day, having developed auricular fibrillation at operation. Her enlarged heart weighed 18 oz., and the mode of death was characteristic of progressive cerebral anæmia, a state emphasised by Howell (1944).

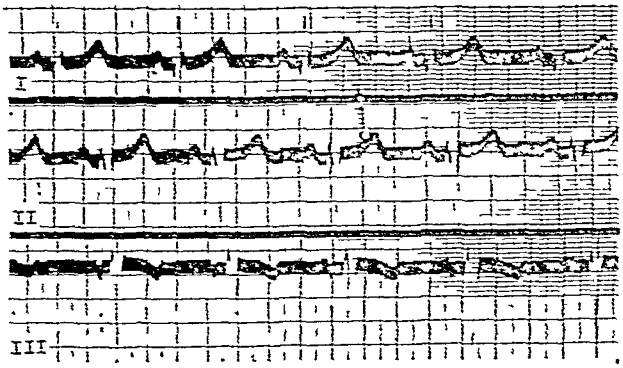


Fig. 14—Normal rhythm in woman aged 73 with left axis-deviation: T I and II well developed; T III negative. This type of record demands further investigation with deep inspiration and chest leads.

In 4 of the 9 fatal cases the patients died within twenty-four hours of operation, 3 from shock and 1 from massive collapse of both lungs.

The highest blood-pressure in the fatal cases was 160/110 mm. Hg. It is my impression that, provided the heart is not much enlarged and arteriosclerosis not pronounced, old people with hypertension stand operations as well as, probably better than, non-hypertensive patients. Early treatment of operative shock is vital in both classes. Modern anæsthesia is so good that much more can be undertaken than formerly; and, if postoperative bronchopneumonia develops despite breathing-exercises, penicillin and sulphonamides control it and so save the heart both a mechanical and a toxic burden.

It must be remembered that the physician sees a higher percentage of pathological hearts when called to surgical cases than is found in the general surgical series, for the simpler cases are dealt with by junior staff. The physician must have a very good reason for precluding operation in the aged on cardiac grounds, but that operation must be indicated in the true medical sense. White (1946) says:

> "Radical measures of treatment, such as cholecystectomy, are not to be undertaken lightly, hoping to get out

thereby of some such condition as angina pectoris. Emergency operations may be justified, but a cardiac patient may be made worse, with the precipitation even of myocardial infarction or death, by an operation of choice or convenience."

The total assessment of nutrition, build, lungs, and mental outlook is as important as that of the heart in the average elderly patient.

Pulmonary Embolism.—Only 2 patients in my surgical series had pulmonary embolism, both after cataract extraction, and neither was fatal. Pulmonary emboli undoubtedly contribute more often to postoperative death than is clinically suspected. A pulmonary infarct may be relatively "silent," the aged person simply deteriorating in a general way rather like that seen in progressive cerebral anæmia. An unexpected tachycardia may be the only sign, or a "faint" may be precipitated by an embolus. Radiography helps in doubtful cases when a characteristic shadow appears, but its absence does not exclude an infarct.

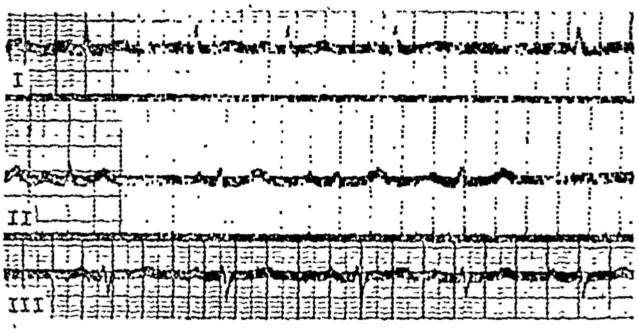

Fig. 15—Sinus arrhythmia in man aged 89 with left axis-deviation.

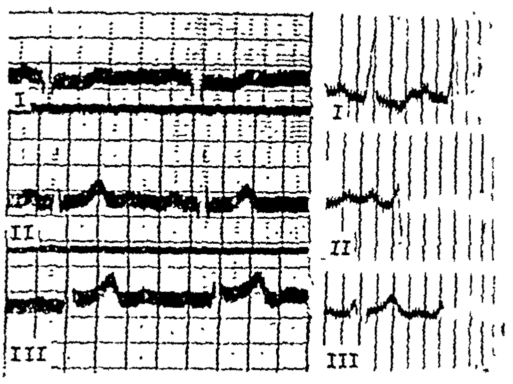
Non-fatal Cardiac Arrest.—A man, aged 70, with carcinoma of the bladder, had cardiac arrest during operation. The heart was immediately massaged, the man recovered, and the abdomen was closed. A few minutes later an electrocardiogram revealed bundle-branch block of the common type but showed no prolongation of the P–R interval to suggest that heart-block had occurred. The patient recovered from the anæsthetic in the usual way and was alert and remarkably well with no new signs. The electrocardiogram did not alter then or three months later, when the operation of prostatectomy and radium insertion was performed uneventfully. The risk was taken because relief from distressing local symptoms was imperative. This case emphasises the fact that the cerebral circulation and brain in the aged can sometimes recover from anoxæmia in a remarkable way. It is the more striking because there was widespread arteriosclerosis; the anterior and posterior tibial arteries had no palpable pulsation. This is a further example of the patchy distribution of arteriosclerosis in the aged.

Prostatectomy is in a class apart, and in modern surgery no man need be deprived of such great relief because of mere old age. No man is too old for prostatectomy. Decision rests on surgical and general medical grounds. A sample of 50 consecutive prostatectomies, excluding 2 deaths, shows that 17 of the patients were aged 70 or more (Millin 1947).

Saline Infusions.—A word of warning may be given here about postoperative infusions of saline when there is a possibility of incipient or masked central cardiac failure in the aged. Slight œdema of tissues caused thereby may turn the scale against the patient, who succumbs to pulmonary œdema of cardiac origin.

Injuries.—Contusion of the chest very easily induces auricular fibrillation in the old, and many examples were seen in air-raid casualties during the war.



(a) (b)

Fig. 16—Electrocardiograms of man: (a) at age of 71; showing increased hypertensive changes.

GENERAL MANAGEMENT OF AGED CA PATIENT

I have referred to this in dealing with heart-failure, but I now wish to emphasise a ciples. Above all we must treat the patient and diagnosis. Important as this is at any age, it in the old. For this reason we should not help from lay observers who have been long in with our patient; their appraisal of the patient less often of his disease) is so often right. Yet attitude is too often pessimistic, simply because old is wrongly regarded as a disease, and the should bring an atmosphere of optimism possible.

The autonomic and vascular systems are unstable in the old and not considered often. True visceral neuroses are common, and old provide the best examples of them. With management they are not very disabling; environment is unsatisfactory and an incorrect at is adopted by those round the patient, his is assured, when more serious illness sets in, by ting peripheral circulatory failure. The patient angina pectoris, for example, has enough to bear; if a visceral (heart) neurosis complicates, as often does, we can at least discuss it with the and save him unnecessary anxiety. There is no that there is room for more optimism and

.e treatment and management of the old than to be thought. Uncertainty is the enemy of ld. All aged persons realise that they have passed verage span of life: and. if the prospect of further is reasonable, we need not emphasise the imme- risks, for Cicero (*De Senectute*) says: "There is no young man who can promise himself that he live until sunset."

ough I have spoken as if the old are fearful of -disease. yet there are not a few who readily accept inevitable and as a complete explanation of troubles remote from the heart. It is imperative to ascertain d man's attitude to life if we are to help him. Much can be done by radical alteration of a patient's ronment; and, if conditions permit, it is best for to remain among his family and belongings. ession, which is so powerful an agent in the old, is by obviated.

insbury (1906) says an old person should lead a life mplative. not executive; but this does not mean ivity. Exercise, mental and physical, is salutary. nterest in the modern world should be encouraged. I recall the ancient councillor, aged 92, who remarked dubious project: "That is reactionary, not progress." discrimination is to be respected in the old.

make a plea for more study of the cardiology of age, for on the circulation all tissues ultimately nd.

e treat disease by rest, but what is the optimal unt of rest? It is very questionable whether the heart that has survived the shock of a coronary mbosis should be rested as long as the younger. ure of the heart after coronary thrombosis is in the old, probably because the demand made on so small, shortness of breath and faintness occurring readily before the heart is strained. Old age, as were, modifies the impact of exercise on the heart. complete rest is overdone, there is risk of further mbosis due to stasis of the circulation. and mural and emboli therefrom or from pelvic veins occur. Younger patients, in contrast, are more mobile. and muscular action in particular is so much more active even at rest, and stasis does not easily occur. If there is heart-failure after coronary thrombosis, there is no choice. The patient must stay in bed; but, if progress is satisfactory, three weeks in bed after coronary thrombosis in an aged person is the optimum required, and the use of a commode may be started after a week in some cases. Naturally the type of person will determine whether he shall be treated more like the younger or more like the oldest groups. A limited period of complete rest seems the more justified because coronary thrombosis in the aged is not so often associated with a large heart as in the young, and so the risk of congestive failure is considerably smaller.

The cause of death after initial survival from coronary thrombosis is probably different in the various age-groups, as I have indicated, and this needs further investigation. The reason why old persons who have survived the shock of a fractured femur do not develop coronary thrombosis more often after protracted rest in bed is that, being old, their vessels are patent enough even if sclerosed, and there is no factor determining thrombosis within the heart such as there is in a patient who has just survived coronary thrombosis.

Another problem is that of auricular fibrillation and the use of quinidine. Should one try to restore normal rhythm, and so remove that strain on the heart, but in so doing allow the appearance of angina of effort? We know that many patients with angina lose it when fibrillation comes on. As I have shown above I think that the indication for quinidine in auricular fibrillation of the aged is confined to postoperative auricular fibrillation, and I here add thyrotoxic fibrillation not removed by operation or by thiouracil.

Those are the kind of problems in old age which deserve much more extensive study. Finally, there is need for investigation of the aged heart that is not diseased, and a better knowledge of the stresses and strains to which it can be put without distress will help in the treatment of pathological hearts. It is remarkable, for example, how well old patients have tolerated electro-convulsive therapy for mental disorders (Moore 1947).

Let us study too the life histories of those of whom it may be said, as of Samuel Paget by his son Sir James (Paget 1901):

> "I had his good counsel and example till he died, at 82, of that most rare of all the causes of death—mere old age. He had never once been ill, and in the time of his gradual decay, nothing erred from its just proportion in the work of life; only there gradually became less of everything belonging to this life, and in due time everything slowly and coincidentally ceased."

SUMMARY

The results of a personal study of 360 patients aged 70 or more (34 over 80) are analysed and discussed. These include 100 eye-cases referred for general medical examination.

Among the ætiological types of heart-disease hypertension and coronary disease were dominant. The average blood-pressure was 188/102, and two-thirds of the patients were hypertensive.

Arteriosclerosis, common enough, was less often advanced than generally thought, and about a tenth had clinically normal vessels and no hypertension.

No useful clinical correlation was found between the various degrees of arteriosclerosis in different parts of the body—e.g., between retinal and radial arteries.

Congestive heart-failure, present in 12·7%, remained amenable to the usual forms of treatment, and the partnership between digitalis and mercurial diuretics remained firm.

LEGENDS TO ILLUSTRATIONS ON PLATE

DR. STANTON, DR. WILKINSON

1—Lateral radiogram showing calcified petrosphenoidal ligament.

2—Radiogram taken in Towne's position and showing calcified etrosphenoidal ligament.

DR. EVANS

1—Slight enlargement of the heart and much pulmonary congestion om cardiac infarction.

2—Moderate enlargement of the heart and pulmonary congestion om cardiac infarction.

DR. WOOD, DR. ANDREWS

1—Marrow showing supersession of marrow by fine fibrosis (case 1). Hæmatoxylin and eosin, × 150.)

2—Lower end of femur (case 2) showing great increase of bony rabeculæ and foci of metastatic bone-formation (indicated by arrows). he place of the marrow is largely taken by degenerate eosinophilic aterial. (Hæmatoxylin and eosin, × 22.)

3—Sections of bones at same level at lower end of femur: (*a*) arrow rim of cortex and great increase in density of spongiosa, ving homogeneous appearance (case 2); (*b*) almost complete lling of medullary cavity with coarse bony trabeculæ (case 1);) from a case of acute myeloid leukæmia in which there was some of the corticalis but no increase of bony trabeculæ in medullary cavity, which was filled with hyperplastic marrow.

DR. ROSENTHAL

ig. 1—Four days after admission. The left lung field is unequally dense, but the base is translucent posteriorly, and there is a dense patch in middle zone of right lung.

2—Taken three days before start of streptomycin therapy. The right lung has cleared considerably. Two large cavities in left lung contain fluid.

3—Film taken on May 7, 1949, after four weeks' streptomycin therapy and three weeks' postural drainage. The cavities in the left lung are closing and do not contain fluid. There is mediastinal shift to the left.

Electrocardiographic and radiological studies not uncommonly revealed normal appearances by standards accepted for young adults, suggesting that these standards remain correct for old age, though minor departures can have less prognostic significance.

The problems of operative risk are illustrated, and the general management of old patients reviewed.

The field for further investigation of the cardiology of old age is explored.

I wish to acknowledge collectively my indebtedness to all my chiefs and colleagues, medical and surgical, at the three hospitals mentioned, for the privilege of examining some of their patients; and to Sir John Parkinson in particular, to whom I owe my basic experience of cardiology.

FAMILIAL CALCIFICATION OF THE PETROSPHENOIDAL LIGAMENT

JOHN B. STANTON
M.A., M.B. Camb., M.R.C.P.
MEDICAL REGISTRAR

MARCIA WILKINSON
M.A., B.M. Oxfd, M.R.C.P.
LATE MEDICAL REGISTRAR

MAIDA VALE HOSPITAL FOR NERVOUS DISEASES

With illustrations on plate

WE report here a family of twelve adults, all of whom showed radiological evidence of calcification of the petrosphenoidal ligament.

Calcification in the dura mater has been described by many writers, including Ström (1920), O'Sullivan (1925), Camp (1930), and Dyke (1930). In nearly all cases the calcification described has been in the falx, and calcification in the tentorium has received little attention. Ström (1920), in his extensive review of intracranial calcifications, does not mention calcification in the tentorium, and Halstead and Christopher (1923) state that this is the rarest form of dural calcification. On the other hand, Camp (1930) writes that in his experience calcification is common in the tentorium, particularly in the portion between the dorsum sellæ and the petrous part of the temporal bone. This site for calcification is also mentioned by O'Sullivan (1925 Löw-Beer (1932). Quain (1915) describes this the tentorium as a fibrous band extending from forepart of the superior border of the petrous part the temporal bone to the lateral margin of the do sellæ of the sphenoid bone. He calls this the pet sphenoid ligament and states that in rare cases becomes ossified, thus completing a foramen which pass the inferior petrosal sinus and the cent nerve. This ligament is sometimes called petroclinoid ligament.

Since no figures are given by the workers cited for frequency of calcification in the petrosphenoidal ligame we have examined 783 normal skulls radiographic for this feature. The calcification is best seen in lateral radiogram (fig. 1), but may also be seen Towne's position (fig. 2).

We have divided the calcifications into three grades

Grade 1, in which there is only slight evidence of calcifi tion, usually taking the form of a hook directed backward and downwards from the posterior clinoid process.

Grade 2, in which there is a greater degree of calcification but it is incomplete.

Grade 3, in which there is an unbroken line of calcificatio running from the posterior clinoid process to the apex of th petrous part of the temporal bone.

The results of this investigation are as follows:

Total no. of normal skulls	783
No. showing calcification of petrosphenoidal ligament:	
Grade 1	63 (
Grade 2	26 (
Grade 3	8 (
Total	97 (

To determine if the degree of calcification in t petrosphenoidal ligament is proportional to that in oth intracranial sites, we examined radiograms of 227 sku with evidence of calcification in the falx, other pa of the dura, or the choroid-plexuses, and obtained t following figures:

Total no. of skulls showing other intracranial calcification	227
No. showing calcification of petrosphenoidal ligament:	
Grade 1	30 (
Grade 2	9 (
Grade 3	5 (
Total	44 (

Skulls showing calcification in the pineal body with calcification elsewhere have not been included in t group, because of the high incidence of calcification the pineal body—51% (Dyke 1930). Our results sh a positive correlation between frequency of calcificat in the petrosphenoidal ligament and of that elsewh in the cranial cavity.

The family which we describe shows a remarka high incidence of calcification in the ligament.

A family of Russian Jewish descent and domiciled England for the last 45 years came to our notice when t members attended the outpatient department of Maida V Hospital for treatment. One had epilepsy and the ot migraine, and in the radiograms of their skulls each sho grade-3 calcification of the petrosphenoidal ligament. other members of the family are in good health except father, who for several years has had bronchitis and he failure. Radiography of their skulls gave the follow results: in the first generation, the father showed grad and the mother grade-1 calcification; in the second gen tion of nine siblings, five showed grade-3, three sho grade-2, and one showed grade-1 calcification; in the th generation four members were examined, one of whom girl aged 18—showed grade-1 calcification, and the ot —all children under the age of 12 years—showed calcification of the ligament.

We have described this family because we have b unable to find any published reference to a fami tendency to calcification of the petrosphenoidal ligam ır as we can determine, the calcification has no al significance.

wish to thank Dr. W. Russell Brain and Dr. J. W. D. for their advice on the presentation of this report, and D. Webb for preparing the radiograms.

PLE HEART RHYTHM AS A SIGN OF CARDIAC PAIN

William Evans
M.D., D.Sc. Lond., F.R.C.P.
ICIAN TO THE CARDIAC DEPARTMENT OF THE LONDON HOSPITAL AND TO THE NATIONAL HEART HOSPITAL; CONSULTING CARDIOLOGIST TO THE ROYAL NAVY

With illustrations on plate

salient cardiac infarction the chest pain is both ng and lasting, and the widespread injury to the rt produces physical signs which are easy to discover. ıs, the patient is pale, cold, and usually sweating er the stress of almost unbearable pain; the temature at the time is below normal, the pulse is small, the blood pressure has fallen; the heart sounds are ant with triple heart rhythm, and occasionally a icardial friction sound is heard; the electrodiogram in such a patient is abnormal, giving proof he diagnosis.

Vith the other kind of chest pain, from *restricted* diac infarction, there are no such obvious physical ns. The pain itself is less severe, neither lasting as g nor causing symptoms of shock; often the pain is y induced by effort and quickly yields to rest; patients remain ambulant and they may make only ual reference to their disability. Up to now the ntification of coronary artery disease in patients hin this group has not been helped by clinical amination, and it has been left to electrocardiography decide the diagnosis.

It was this paucity of clinical signs which led to a re critical examination of the symptoms and signs in tients with chest pain and without either valvular disease or hypertension. Of 285 such patients examined in 1948, in whom the character and the situation of the pain, along with its relation to effort and to rest, made it likely that it was cardiac pain arising from coronary artery disease, in 139 the electrocardiogram was physiological and no abnormal physical signs were found. In the remaining 146 a subsequent electrocardiogram showed evidence of cardiac infarction, confirming the presence of true cardiac pain in each. In this group patient after patient showed a characteristic triple heart rhythm on auscultation, and it soon became apparent that triple heart rhythm in any patient with chest pain predicted unerringly the electrocardiogram identified with cardiac infarction. Triple heart rhythm was specially examined for its characteristics and for the conditions which determined its presence.

BLE I—CLINICAL SIGNS IN 285 PATIENTS WITH SYMPTOMS TYPIFYING CARDIAC PAIN, 146 OF THEM WITH CARDIAC INFARCTION. OPEN FIGURES DENOTE NUMBER OF CASES AND BRACKETED FIGURES DENOTE APPROXIMATE PERCENTAGE

Clinical state	Cardiac infarction 146		Chest pain, with normal electrocardiogram but never with triple heart rhythm 139
	Dual heart rhythm 105 (72%)	Triple heart rhythm 41 (28%)	
ood pressure:			
High normal	20 (19%)	2 (5%)	Variable
Normal	83 (79%)	36 (88%)	
Low	2 (2%)	3 (7%)	
ature of pain:			
Brief and only on effort	22 (22%)	5 (12%)	64 (46%)
Long and at rest ..	83 (78%)	36 (88%)	75 (54%)
lace of infarct:			
Anterior	32 (30%)	16 (39%)	Normal tracing
Posterior	43 (41%)	16 (39%)	
Lateral	22 (22%)	7 (12%)	
Various	8 (7%)	2 (10%)	
ardiac enlargement ..	37 (35%)	27 (65%)	None
eart failure	7 (6%)	20 (49%)	None

NATURE OF THE TRIPLE HEART RHYTHM

That a triple heart rhythm occurs early in cardiac infarction is known (White 1928, Parsonnet and Hyman 1931, Thompson and Levine 1936, Master et al. 1937), and it is only necessary to emphasise its common incidence in patients where cardiac infarction sets in abruptly and is accompanied with severe shock. But this paper is concerned with the ambulant patient who is susceptible to chest pain during effort, especially walking (cardiac ischæmia or angina pectoris of effort), which is quickly relieved by resting, or which occasionally comes while at rest, lasting a little time but not causing distress.

TABLE II—INCIDENCE OF CARDIAC ENLARGEMENT AND HEART FAILURE IN 146 PATIENTS WITH CARDIAC INFARCTION. FIGURES DENOTE NUMBER OF CASES

Incidence of cardiac enlargement and heart failure	Cardiac infarction 146	
	Dual heart rhythm 105	Triple heart rhythm 41
Cardiac enlargement alone ..	31	10
Pulmonary congestion alone ..	1	3
Cardiac enlargement and pulmonary congestion	6	17
No cardiac enlargement and no pulmonary congestion ..	67	11

Audibility

The triple heart rhythm was sometimes moderately loud, but generally it was less well heard, and it is for this reason that the sign, if not elicited easily, should be sought deliberately. *Induced tachycardia* caused the triple rhythm to become more distinct, but seldom did this test bring the added sound into being when it had been absent with a normal heart rate; yet, since this did at times happen, auscultation should be carried out after exercise if at the first examination only two heart sounds are heard. The triple rhythm was always better heard in the *reclining posture* in those cases where it was present in the upright posture as well. In the majority of patients, however, the sign was only found in the reclining posture. It was best heard at the *lower end of the sternum*, and where the triple rhythm was elicited only by careful auscultation it was confined to this area. When the auscultatory sign was more distinct it was audible towards the mitral area as well.

Incidence

Among the ambulant patients with chest pain which historically presented all the characteristics of cardiac pain there were 146 in whom a subsequent electrocardiogram showed clear evidence of cardiac infarction. A triple heart rhythm was present in 41 (28%) of these; in the remaining 105 cases only two heart sounds (dual heart rhythm) were heard.

Ætiology

Neither the *sex* nor the *age* of the patient influenced the incidence of triple heart rhythm. The *frequency* with which the sign was met with in cases with *extensive* or salient cardiac infarction made it likely that in the present series of ambulant patients the sign would be commoner in those in whom the *onset of pain* had been recent; no such association, however, could be made out.

The state of the *blood pressure* was next considered, it being understood that no patient with hypertension was admitted into the series; hence none had hypertensive cardiovascular hypertrophy, cardiographic evidence of left ventricular preponderance, or a previous record of raised blood pressure. The cases were divided into three groups according to whether the blood pressure was a high normal value (e.g., 165/95), a normal value (e.g., 130/90), or a low value with a systolic pressure of 110 or under. Though the incidence of a low blood pressure was not significantly greater in patients with triple heart rhythm than in those with dual rhythm (7% against 2%), table I shows that the proportion with a high normal blood pressure was small among patients with triple rhythm (5% against 19%).

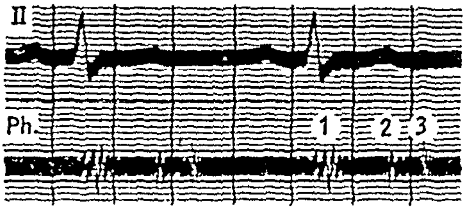

Fig. 3—Triple rhythm from addition of the third heart sound in cardiac infarction. Lead II of the electrocardiogram and the phonocardiogram are shown in this and subsequent figures.

When the *duration* of the paroxysm of pain and its onset while the *patient was at rest* were considered in relation to the added heart sound, it was found that, when the pain was induced only by effort and quickly yielded to resting, triple heart rhythm was less often present (12%) than when the attacks lasted longer and came on while the patient was at rest (88%). Since cardiac infarction was present in both groups, the longer attacks, with a higher incidence of triple rhythm, appeared to initiate triple rhythm not because of the duration of the pain but because the pain lasted longer if cardiac enlargement and heart failure were also present.

The *site of the infarct* appeared to have no influence in deciding the presence of triple rhythm, for a slightly higher incidence in anterior infarction and a slightly lower one in lateral infarction are not regarded as significant.

Cardiac enlargement, on the other hand, played a part in initiating the triple heart rhythm of cardiac infarction, for it was almost twice as common in patients with triple rhythm (65%) as in patients with dual rhythm (35%).

The incidence of *heart failure*, judged from the presence of pulmonary congestion on cardioscopy, was even more significant, because it was present in 49% of patients with triple rhythm and in only 6% of those with dual rhythm. Though this auscultatory sign w the absence of both cardiac enlargement and it was more likely to be present when either ditions presented, especially heart failure, larly if both occurred together (table II and fi

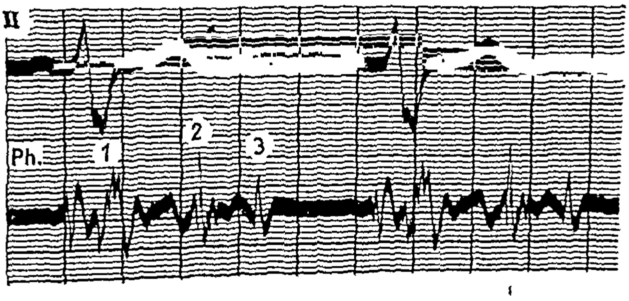

Fig. 4—Triple rhythm from addition of the third heart sound in cardiac infarction.

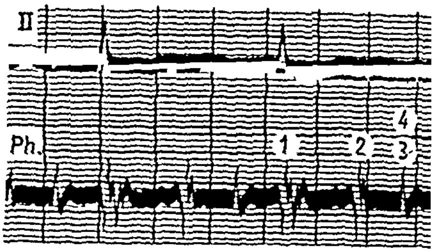

Fig. 5—Summation triple rhythm where the fourth h auricular sound coincides with the third heart sou delayed A-V conduction, which has lengthened the the electrocardiogram.

DIFFERENTIAL DIAGNOSIS

The triple heart rhythm in cardiac infarc from the addition of the third heart sound (fi and as a rule no ancillary test beyond clinical is required to discover it. Indeed a triple rh adult with chest pain which is brought on by ph usually points to cardiac infarction. Triple he can, however, be simulated by two other con

In the first there is a delay in auriculo conduction of the cardiac impulse, which is prolongation of the P–R period in the electro and in this event the auricular or fourth heart earlier in diastole and near to the second h giving the impression that it is the third (fig. 5). For the diagnosis of this form of tri an electrocardiogram is necessary, though general distribution of this sign over the hea presence in the upright as well as in the reclini should give a clue.

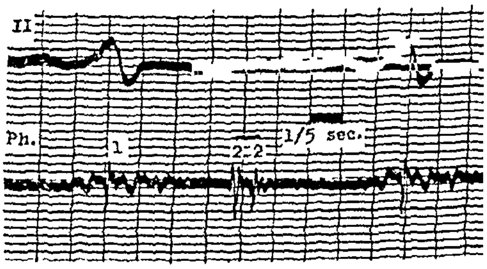

Fig. 6—Splitting of the second heart sound in bundle b

The second condition which may giv difficulty in diagnosis is bundle branch bl causes splitting of the second heart sound (fig additional sound in this instance, however, is the second heart sound, and, though a phono may be required to confirm the auscultatory whenever tachycardia frustrates its clinical r the finding of bundle branch block in th cardiogram is sufficient to infer this mechanis extraneous sound. Naturally the presence branch block in a patient with chest pain ma suggest that cardiac infarction has given ri auscultatory sign.

SUMMARY AND CONCLUSIONS

Owing to the paucity of physical signs, the of cardiac pain in a patient subject to recurren fort in the chest has hitherto been considered i without electrocar ɔain, and its relation to effort and to rest, cannot to distinguish cardiac pain from that which has a obscure origin and a less ominous meaning.

dia [illegible] of triple heart rhythm on [illegible] ested in 285 consecutive its with chest pain, in 146 of whom a subsequent ocardiogram showed cardiac infarction.

ole heart rhythm from addition of the third heart is of inestimable value in diagnosis. Its presence lower end of the sternum with the patient in the ng posture, provided by itself a diagnosis of c infarction in 41 out of 146 cases where the ocardiogram gave proof of infarction.

ong the factors which might determine the presence le heart rhythm in a patient with cardiac infarction, only—cardiac enlargement and especially heart , showing as pulmonary congestion on cardioscopy tributed to the appearance of this auscultatory Though triple rhythm was sometimes present ut either, it was more likely to be found in cardiac tion when heart enlargement and failure existed y side.

help obtained from triple heart rhythm in the osis of cardiac infarction as the cause of chest pain d encourage the clinician to seek it diligently. with the bell of the stethoscope at the lower end of ernum he must ask himself: “ Do I hear the third sound?” From such deliberate self-catechism in case a clinical recognition of cardiac infarction is le in over a quarter of the patients with chest pain iom a subsequent electrocardiogram confirms the osis.

SUBACUTE MYELOSCLEROSIS

REPORT OF THREE CASES

EILEEN E. WOOD
M.R.C.S.
HÆMATOLOGIST

C. T. ANDREWS
M.D. Belf., F.R.C.P.
PHYSICIAN

WEST CORNWALL GROUP OF HOSPITALS

With illustrations on plate

LEROSIS of the bone-marrow is associated with us clinical conditions. It is a not uncommon npaniment of refractory anæmia associated with co-erythroblastic blood picture. It is found in cases nting clinically as leukæmia or aleukæmic leukæmia still more commonly in those cases described by ling (1937) and others as non-leukæmic myelosis. is also been described in exhaustion states of the -marrow, particularly those associated with tuber-is (Crail et al. 1948), and has been attributed to ication by fluorine, lead, arsenic, phosphorus, and ne dyes (Jacobson 1933).

yelosclerosis must not be confused with osteopetrosis arble-bone disease, described by Albers-Schonberg 4), in which there is excessive calcification of the ex with defective ossification as shown by absence one lamellæ and osteoblasts. Pathologically the ntial finding in myelosclerosis is an obliteration of marrow cavity by connective tissue either fibrous ony. Fibrous tissue takes the place of the cellular row, and this may or may not be followed by the ng down of bone in the fibrous reticulum and by the elopment of osteosclerosis.

RELATION TO LEUKÆMIA

n cases presenting as leukæmia it appears that fibrous ue follows intense cellular proliferation. Except in the rare form of monocytic leukæmia osteosclerosis does not often occur. In non-leukæmic myelosis a true osteosclerosis of the marrow is more common, and the medullary cavity may be found almost obliterated by a close network of bony trabeculæ so dense that little or no marrow is left in the meshes. Unlike the condition in marble-bone disease there is little cortical involvement. In fact there may be areas of osteoporosis and the radiographic appearance may suggest that the proliferating spongiosa is invading the cortex.

This type was first described by Heuck (1879). Much controversy has centred on its relation to the leukæmias, with which it is often confused clinically. Thus Heller et al. (1947) conclude that the criteria alleged to differentiate the two disorders do not withstand critical analysis. Vaughan and Harrison (1939), however, take the view, with which we agree, that myelosclerosis arises at a more primitive level of hæmopoiesis than does leukæmia. They postulate a stimulus to the reticulum cell of Maximow, which is the precursor of osteoblasts, fibroblasts, hæmopoietic cells both myeloid and erythroid, and giant megakaryocytes. This theory finds support from the wide variety of tissue response seen, from the presence in the peripheral blood of primitive cells such as hæmocytoblasts, and from the occasional presence of a polycythæmic and leukæmoid blood picture in the same case (Windholz and Foster 1947). Though the distinction between the two groups of cases appears at present to be academic, in future it may be of some importance, for one of them may be more responsive than the other to new forms of therapy, with a resulting difference in prognosis.

INCIDENCE

The incidence of myelosclerosis is difficult to assess. In cases of obscure anæmia, even today, the long bones are seldom radiographed and necropsy is not always complete. The recent literature suggests that myelofibrosis is much commoner than osteosclerosis. Churg and Wachstein (1944) reviewed 97 cases of leukæmia retrospectively and found that 6 showed myelofibrosis and 1 osteosclerosis. Hickling (1937) states that it is not at present possible to know how frequently osteosclerosis occurs in cases of myelosis (leukæmic and non-leukæmic). In both groups there are acute and chronic cases. He says there seems to be no clinical or hæmatological factor by which osteosclerosis can be demonstrated.

CLINICAL PICTURE AND HÆMATOLOGY

Clinical and hæmatological features have varied widely in the cases described. The great majority have run a long course and most of the patients have been elderly. Thus Sussman (1947) described 9 cases in late adult life; all ran a protracted course. A case reported by Windholz and Foster (1947) lasted thirty years. Hickling (1937) described 7 cases, all in late adult life: all ran a protracted course.

In the few acute or subacute cases described the age-incidence has tended to be lower and the course shorter. Thus Goodall (1912) described the case of a child, aged 2 months, with a leukæmoid blood picture in which multiple hæmorrhages, purpura, stomal ulcers, and moderate splenic enlargement were present. Death took place a few weeks from the onset, and necropsy revealed a remarkable degree of osteosclerosis affecting the humerus, femur, sternum, and ribs. Windholz and Foster (1947) describe a case of acute lymphatic leukæmia with osteosclerosis, which they claim to be the third of this type.

The patient was a boy aged 16, and the diagnosis was based on a white-cell count of 15,000 per c.mm., 82% being lymphoblasts. The illness, characterised by progressive weakness, hæmorrhages, jaundice, and enlargement of cervical glands and spleen, was fatal in nine weeks from the onset. Well-marked radiological evidence of osteosclerosis was found in *vertebræ, long bones, ribs, and pelvis.*

Cases have also been described by Jacobson (1933), Hässler and Krauspe (1933), and Rosenthal and Erf (1943). Follis et al. (1942) reports osteosclerotic changes in 5 cases of erythroblastosis fœtalis.

Our purpose in recording 3 cases of this type is to draw attention to the possibility of myelosclerosis as a complicating factor in cases of refractory anæmia and to the early development of bony changes. The clinical and hæmatological picture in these 3 cases differed considerably. All 3 patients died after comparatively short illnesses. In 2 of them radiological evidence of osteosclerosis was obtained during life. Our first case presented as a pyrexia for which no obvious cause could be found; there was a refractory anæmia, a few primitive leucocytes were found in the blood, and there were some bony changes. During the course of her illness this girl developed well-marked osteosclerosis with a hypoplastic bone-marrow. Splenomegaly was never a prominent feature and only occurred towards the end.

FIRST CASE

A girl aged 16, a grocer's assistant, was quite well up to Christmas, 1946, when she began to run a slight temperature in the evening and had pain in the right knee and thigh. At this time also she started to lose weight and looked pale. Menstruation, which had been scanty for three months, now ceased. She developed a papular rash, thought to be scabies, but this disappeared in a week and did not return. Pain at this time was severe, keeping her awake at night, and acute rheumatism was provisionally diagnosed by her doctor. Subsequently persistent localisation of pain in the right thigh region led to consideration of the possibility of osteomyelitis and radiography was undertaken to exclude this. The patient became progressively weaker towards the end of March and was admitted to hospital with a swelling of the right knee. Her temperature at this time showed an evening rise to 100°F and in subsequent weeks reached 102°F on several occasions. There was nothing relevant in her past or family history.

On examination the patient was thin and wasted, complexion and mucosæ. Pulse regular at 100; blood 120/65; heart normal in size clinically, with no bruits spleen, and kidneys not felt. No abdominal t right knee was swollen, without discoloration, and free fluid; it was painful on flexion. No glandular en was detected.

Blood.—A blood-count before admission gave the f figures:

Hæmoglobin	..	11%	Myelocytes	.. ..
Red cells	..	2,660,000 per c.mm.	Metamyelocytes	.. ..
White cells	..	5100 per c.mm.	Polymorphs	.. ..
			Monocytes	.. ..
			Lymphocytes	.. ..
			Eosinophils	.. ..
			Basophils	.. ..

Subsequent blood-counts are shown in the accompan table. The erythrocyte-sedimentation rate was 125 mm. in the first hour and 150 mm. in the second (Westergren).

Sternal puncture was attempted, the needle being introd into two tender areas in the sternum. There was d resistance to the entry of the needle, and the material drawn consisted of much blood with only scattered m cells, in which the predominant cell showed a large nu in which the nuclear chromatin was condensed into a sieve-like arrangement and there were exceptionally nucleoli. The cytoplasm was reduced in amount and Red-cell precursors were scanty. The possibility of mye or myelosclerosis was considered, and the long bones radiographed.

Radiologically there was some increase in density o femoral condyles and of the upper ends of the tibiæ. appeared to be some laying down of bone on the inner s of the cortex in the upper thirds of the tibiæ. There was irregular increase in density in the bodies of both tali a the juxta-articular bone of the tibia; punctate decalcific was observed in all the tarsal bones. The bone changes most marked round the ankle-joint, and the radio reported that he would have passed all the bones o these as within normal limits. An X-ray film of the femur taken after death showed irregular increase in de with the inner margins of the cortex ill defined (fig. 4).

Sternal puncture was again attempted in June, manubrium felt slightly less abnormal than the body

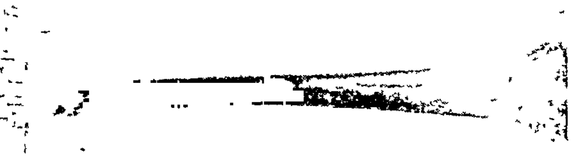
* Basophils nil in all counts. † Per 100 white cells.



—Right femur, radiographed after death, showing generalised ease in density, with almost complete obliteration of the lullary cavity in upper half.

ow cells were rather more numerous than before. There very few recognisable erythroid cells. The characteristic vas thought to be a hæmocytoblast; several of these were found in division, one showing four nuclei. There a hiatus between these cells and a few myelocytes and myelocytes. There were, however, some small round resembling lymphocytes, which may have been myelo-s.

atment with blood-transfusions was started on May 10. one two-pint transfusion there was some improvement. May 22 hæmoglobin had gone up to 54% and the red-cell t was 4,800,000 per c.mm. Further blood-transfusions two pints on June 2 led to a hæmoglobin reading of 71%, this had dropped to 50% on June 10, and further blood-fusions of two pints each on June 16, July 7, and July 18, three pints on July 31 led to no material improvement. last blood-count, on Sept. 1, showed Hb 21% and cells 1,120,000 per c.mm.

ogress.—Throughout the illness limb pains and inter-ent swelling of joints were prominent, and pain was etimes so severe as to require morphine. There was ressive emaciation, and the patient lost several stones in ht. Her temperature towards the end showed irregular to 103° but there were periods of upwards of a week when as normal. She died on Oct. 3, 1947.

NECROPSY FINDINGS

he body was that of an emaciated girl whose skin showed ead white pallor. There were no bruises or petechiæ. lost all the superficial fat had disappeared. The joints wed no abnormalities. Axillary and inguinal lymph-glands e palpable. Mediastinal glands were slightly enlarged, h superficial hæmorrhages. Mesenteric glands were rged, flat, and whitish. Para-aortic glands showed small erficial hæmorrhages. Sections from several glands all wed loss of normal architecture, and some showed coarse nds of fibrous tissue, only small fragments of lymph icles remaining. Silver impregnation showed a rather rse reticulum with few cells in the interstices. Megakaryo-es appeared in a few of the glands in small clusters. Red-precursors were scanty, and the predominant cell was of cular type with a large irregular vesicular nucleus.

he *lungs* were pale, with numerous small bright-red norrhages on the surface. There was no evidence of erculous infection. The *cardiovascular system* showed no croscopic abnormality, except that the diameter of the ta was significantly reduced.

The *liver* was not enlarged and was pale pinkish-brown with merous opaque miliary nodules giving a fine cream mottling oughout its substances. Microscopically there was a fine rosis in the portal areas with deposition of pigment in the er cells, most marked in the periphery of the lobules. the periportal areas there were infiltrations of cells, some n being of considerable size; myeloid cells were also ttered through the liver sinusoids. Erythroid precursors re numerous, and a few megakaryocytes were seen. One ction showed a tiny metastatic bone-marrow nodule, mewhat necrotic but with numerous megakaryocytes; it as reminiscent of the large tumour found in the spleen the case of megakaryocytic myelosis described by Hewer 937).

The *spleen* weighed 16 oz.; its capsule was smooth and thin, ith a fine white mottling over the surface. On section it as deep red studded with brighter red glistening pinpoint odules. There were no infarcts. Histologically the spleen howed a loss of normal architecture with little obvious ibrosis, though silver impregnation showed an increase of somewhat coarse reticulum. There were many primitive narrow cells lying in the sinuses and in the pulp. Erythroid precursors were scattered, throughout the spleen, though very few islands of young red cells were found; there were a few megakaryocytes but they did not form a prominent part of the picture. Many eosinophils, both polymorphs and myelocytes, were seen, though there had never been an eosinophilia in the peripheral blood.

The *kidneys* were pale but showed no gross changes. Sections showed most extensive infiltration with hæmopoietic cells; these cells formed foci which were destroying the tubules by crowding them out of existence. The histological picture was that of a diffuse extramedullary hæmopoiesis.

Bones.—The sternum showed thinning of the corticalis, with obliteration of the marrow cavity by spongy bone; a few fragments of red marrow were seen in the manubrium only. Two ribs examined showed an increase of bony trabeculæ, but there was rather more marrow in the interstices than in the sternum. Lumbar vertebræ showed increased spongiosa, but a considerable amount of marrow remained. In one vertebra there was a dense wedge-shaped infarct. The femur was a light bone and showed no external abnormalities. Longitudinal section showed thinning of the cortex in the upper and lower third of the bone, with some irregular increase of its density in the middle third. In the upper third the spongiosa showed increased trabeculation, with very little marrow. Irregular spicules of bone projected into the cavity of the shaft, which was much reduced and contained some yellow marrow, with a few flecks of red marrow at intervals. In the lower third of the bone the spongiosa became increasingly dense (fig. 3*b*). There was an infarct in one condyle. The marrow (fig. 1) in sections showed few cells; young fibrous tissue was growing out from the trabeculæ, and silver staining demonstrated a fine reticulum. There was no osteoblastic reaction.

The peripheral blood picture in this case was not truly leukæmic, the first count showing only 8% myelocytes. Two months later 7% myeloblasts were found and a few normoblasts were recorded for the first time. The picture was that of a leuco-erythroblastic anæmia; the characteristic cell in the bone-marrow was a hæmocytoblast, and there were few intermediate forms between these cells and the polymorphs. Towards the end the number of nucleated red cells increased and finally reached 64,000 per c.mm.

SECOND CASE

The second case was accepted clinically as a case of acute leukæmia, but in view of Churg and Wachstein's (1944) contention that osteosclerosis is associated with non-leukæmic myelosis and rarely, if ever, with a true leukæmia we decided to look for bony involvement in all available cases showing a leukæmic or leukæmoid blood picture.

Sternal puncture proved difficult owing to the density of the sternum, and only a small clot was found in the needle, but this contained marrow cells. Examination showed that 47% of these were of the granular series, 31% were small round cells, and 22% were of the erythroid series. Even if the small round cells are all assumed to be micromyeloblasts, the M/E ratio is low for a leukæmia. Unfortunately very little necropsy material was kept, since the findings were thought at the time to be those of a typical leukæmia and to have disproved the theory that osteosclerosis did not occur in these cases. Since that time 4 cases of acute myeloid leukæmia have been carefully investigated, and none of these showed myelosclerosis; 2 other cases have been presumed to have no bony involvement because there was no clinical evidence of it.

A man aged 32, an upholsterer, was admitted on Oct. 21, 1947. He had been feeling run down for three months and had lost weight. Six weeks before admission he had had four teeth removed for pyorrhœa; the sockets bled for three days, and he was notably pale but went back to work. Five days after the extractions he had had an attack of acute spasmodic epigastric pain, which again kept him from work and kept recurring. A week before admission he had had three more teeth extracted, with a recurrence of bleeding, which again lasted three days and was followed by pain in the right knee, which sent him to bed. The knee had become swollen, and the pain had radiated up and down the leg. There was no significant past or family history.

On examination he was pale and his right knee was slightly tender but not swollen. There was slight limitation of flexion. His temperature was 99·6°F, but in the following three weeks it rose to 100–102°F in the evenings. The gums were hypertrophied and oozing blood. There were petechiæ on the hard palate. The liver and spleen could not be felt, and there were no palpable glands.

Radiography of pelvis and long bones showed some generalised increase in density, with patchy opacity at the base of the great trochanter, in the right femur, and some increase in density of the pelvic bones.

Treatment with urethrane, gr. 30 thrice daily, was begun on Oct. 25 and continued until Nov. 11. A blood-transfusion of two pints was given on Oct. 24.

Progress.—On Nov. 11 he complained of pain in the splenic region, and his spleen was now found to be palpable. His condition had gradually deteriorated, and he died next day.

Radiography of right femur after death showed that the head was extremely dense. The neck, greater trochanter, and most of the upper half of the shaft showed a less homogenous increase in density, and the inner margins of the cortex, especially in the middle third of the shaft, were not really distinguishable. The cortex showed small rather linear translucent areas, and the medullary cavity appeared to be almost obliterated by coarse bony trabeculæ.

NECROPSY FINDINGS

The body was that of a well-nourished man; there were no external hæmorrhages and the glands were only slightly enlarged. There were no significant findings in the thorax. The abdomen contained half a pint of unclotted blood. There were large clots of blood round the *spleen*, which was soft and deep pink but not much enlarged. There were one or two rents in the capsule, from which there had been some bleeding. The capsule stripped off carrying with it a double layer of organising blood-clot, suggesting that hæmorrhages had been occurring for two or three weeks. The cut surface showed no infarcts or significant alteration in pattern. Microscopically the spleen was very similar to that seen in case 1, except that there were irregular eosinophilic masses of necrotic cells. There was diffuse extramedullary hæmopoiesis, with no great increase of myeloblasts.

The *liver* showed an entirely different picture. Here there was no extensive infiltration and no evidence of extramedullary hæmopoiesis. There was scanty periportal infiltration with primitive myeloid cells, but this did not appear comparable with the high count of primitive cells in the peripheral blood.

Bones.—The sternum showed thinning of the cortex, with increased density of the spongiosa and only a few flecks of marrow in the fine trabeculæ. The femur was massive and felt heavy in comparison with other femora examined. There was a little pinkish marrow in the upper third but it was difficult to scrape away from the bone. The spongiosa was greatly increased in density and seemed to be developing at the expense of the corticalis. In the middle third there was some increase of density in the corticalis, which on the inner side showed definite thickening, and the medullary cavity here contained some marrow. Below this the spongiosa increased and appeared to be invading the cortex. In the lower third the cortex was reduced almost to eggshell thickness and the spongiosa became very dense, with the result that to the naked eye the trabecular pattern had almost disappeared (fig. 3*a*), there was no demonstrable marrow (fig. 2), and the section of the bone was cream-coloured.

In this case therefore the femur differed considerably from that of the first patient, in that the trabecular pattern was much denser and in the lower third presented a dense homogeneous picture. It seems certain that the bony changes must have been initiated some time before the leukæmoid blood picture developed. Follis et al. (1942) suggest that in the marrow osteosclerosis occurs first, followed by leukæmic or erythroblastic proliferation. This in turn is followed by disappearance of the leukæmic and erythroblastic cells (depopulation of the marrow) and proliferation of fibrous tissue in their place; finally osteosclerosis develops in the area.

It is likely that the extramedullary found in these cases is a response to an excessive on the bone-marrow, which was gradually obliterated by fibrosis and overgrowth of spongy Histologically both cases showed an irregular with marrow cells rather than a diffuse leukæmic of the spleen and glands. The late enlargement spleen in both cases suggests that it occurred as a pensatory process following the obliteration of marrow cavity.

THIRD CASE

The third case presented as an aplastic *After a long period of hypoplasia of the bone-* there were diminishing response to blood-tr and compensatory splenic enlargement.

A boy aged $2^{1}/_{2}$ years, was admitted on Nov. 5, 19 He was the only child of normal parents; his mother had no miscarriages. He had weighed $8^{1}/_{2}$ lb. at birth. T months before admission he had had skin sepsis, with "b and abscesses" in both legs and groins. A month bef admission his nose had bled severely for twelve hours. Fr this time onward increasing pallor was noted; he looked and had a cough. He vomited often and developed a dis from his ears, and loose slimy motions.

On examination he was very anæmic, with moderate wasting and much halitosis. Some small shotty glands were palpable in the neck, axillæ, and groins. The spleen was palpable 2 in. below the costal margin. The mouth and throat wa clean. The left ear drum was perforated and discharg intermittently.

Progress.—During the next few weeks the child suffered considerably from skin sepsis, at first on the lower limbs a later on the face. This was associated with considerable enlargement of groin and cervical glands. His temperature swung irregularly to 102°F. About the end of January h passed four roundworms.

Treatment.—Nine blood-transfusions were given, who blood being used in the early stages, and packed cells late Clinical improvement was definite, but hæmoglobin never ro above 55%. The spleen became much larger about th middle of February; the liver also was palpable at this stage He developed a bronchopneumonia, which did not respond t penicillin, and he died on March 1, 1949.

NECROPSY FINDINGS

Macroscopic changes in the organs were not significant The *spleen* was enlarged, weighed 15 oz., and was deep re and homogeneous in appearance. The *liver* and other organs were pale. There was slight generalised enlargement o *lymph-glands.* The *thymus* was not enlarged. The *thyro gland* was enlarged and showed no obvious colloid.

Sclerotic changes were marked in the *bones.* The marrow cavity of the sternum was filled with dense spongiosa with th *result that no marrow was obtained.* The femur was norma externally and was $7^{1}/_{2}$ in. long. Longitudinal section showe much sclerosis of the head, the density approaching that o a marble bone; the trabeculation became coarser toward the shaft, and in the middle third of the shaft the cavity remained and contained reddish marrow for about 1 in. Below this the trabeculation increased again; it was coarse at first and there was a little marrow in the interstices, but it became increasingly dense in the lower third and seemed to b developing at the expense of the cortex.

Histologically there were no significant findings in the tw glands examined. The thyroid gland showed great hypertroph of the acini, with very little secretion. The *lungs* showed terminal bronchopneumonia only. The *spleen* showed som loss of the normal architecture; red cells were generall scanty, but primitive cells with large, sometimes enormou vesicular nuclei and generally one or two nucleoli wer scattered throughout the section; a few mitotic figures wer seen; and there were groups of eosinophils, both polymorph and myelocytes. Recognisable red-cell precursors were ver scanty. The *liver* showed more definite foci of hæmopoiesis the cells showed some degeneration, but the same primitiv cell was prominent. An occasional megakaryocyte was found

dneys showed no cellular infiltration. The marrow
d from the femur was cellular and consisted chiefly
undifferentiated cells, but eosinophils were a notable
a few nucleated red cells were seen.

istological appearances in this case differed from
the other two in that extramedullary hæmo-
was less prominent and red-cell precursors were
nty. The possibility that this was an aleukæmic
ia has been considered, but the resemblance to
ings in cases 1 and 2 suggests that they should all
sed as myelosclerosis. Case 3 seems to have
s a result of a long-standing refractory anæmia,
starting soon after birth. Rosenthal and Erf
have described similar cases in children. Radio-
finding of myelosclerosis has also been noted by
lz and Foster (1947) in a girl, aged 9 years, with
s anæmia and malaria: the condition here
own to exist for eight years. Follis et al. (1942).
ng well-marked myelosclerotic changes in 5 cases
throblastosis fœtalis, suggest, on the known
in birds between œstrogenic hormone and bone
, that myelosclerosis in these cases may have been
increased chorionic hormone from enlarged
æ. Though Rh incompatibility has been excluded
3, it seems possible from the presence of thyroid
s that an endocrine factor may have been
d.

early appearance of bony changes has been an
ding feature of some cases and suggests that radio-
evidence would be forthcoming if it were looked
he bones most constantly involved are the long
particularly femur, humerus, and tibia, but
s in ribs and skull have also been noted. The total
of the bone is not affected; the inner margin of
tex of the long bones becomes ill defined. The cortex
ow small translucent areas, and the medullary cavity
e almost obliterated by coarse bony trabeculæ
s. 2, 3*a*, and 3*b* and compare with fig. 3*c* from a
acute myeloid leukæmia). The later stage shows a
lised increase in density, with medullary cavity no
distinguishable. In long-standing cases periosteal
ay be formed. In the pelvis the changes are usually
arked in those parts adjacent to the acetabulum
ng 1937). In the skull the frontal bone seems to be
ommonly affected.

iological evidence of bony changes may be found
n acute or subacute cases. They may be present
in the illness or may be seen only just before
They are to be sought particularly in those
in which pain has been a prominent feature, and
most painful areas. Where pain is absent, routine
ation of the upper half of both femora and of the
us, tibia, lumbar vertebræ, and skull should be
l out. Bone-marrow biopsy may be needed to
ete the diagnosis when radiography is negative.

CONCLUSION

elosclerosis as a clinical entity is probably commoner
has been thought. It has long been recognised in
ation with leukæmoid and leuco-erythroblastic
states. In the chronic case splenic enlargement is
well marked. Such cases may be mistaken for
emic leukæmia or splenic anæmia.

more acute cases and in refractory anæmia due to
ing or exhaustion of the bone-marrow its presence
d be considered when limb pains or backache are
minent feature. Long-continued pyrexia associated
a severe anæmia should also bring this possibility
ind. From the cases here presented it seems that
dinal indication of the diagnosis is the finding of
derable difficulty in obtaining bone-marrow by
al puncture. Instead of the usual sharp penetration there is diffuse resistance, and there is no way of knowing when the marrow cavity has been reached.

Splenic enlargement in these acute and subacute cases is variable, but the association of an enlarged spleen with a hypoplastic marrow is sometimes suggestive. So also is the waning effect of repeated blood-transfusions.

STREPTOMYCIN IN FRIEDLÄNDER PNEUMONIA

F. D. Rosenthal
M.B. Lond., M.R.C.P.
HOUSE-PHYSICIAN, GENERAL HOSPITAL, NOTTINGHAM

With illustrations on plate

Infection of the lung with the Friedländer bacillus is rare: it has been variously estimated as the cause of between 0·5% and 4·0% of all cases of pneumonia reaching hospital. Since almost all patients with Friedlander pneumonia are seriously ill, most of them tend to reach hospital, and the total percentage incidence is probably lower than reported. Acute and chronic forms are described, but the chronic is usually the result of the acute. The Friedländer bacillus is also found in some cases of bronchiectasis; its significance then is doubtful, since usually it is only one of several organisms found in the sputum.

Acute primary Friedländer pneumonia is of acute onset and occurs mainly in men aged 40–60, especially those who are debilitated. Cases in women and in other age-groups are, however, not uncommon. The body temperature is relatively low compared with other forms of pneumonia. There is often a well-marked leucopenia. The sputum in most cases is characteristic, being very tenacious and stringy and of a chocolate colour, often mixed with pure blood. Unless the patient dies early from the toxæmia, there is a tendency to cavitation of the lung. The disease is progressive, and until recently the case-mortality, in spite of treatment, was very high.

MORTALITY-RATES

Series published have on the whole been small, with a mortality-rate of 70–97%. The largest series published is that of Zander (1919), who described an epidemic of 411 cases with a mortality-rate of 30%. His patients were mostly young. Since he gave no clinical details and all other series published before 1943 showed a much higher mortality, judgment on this article must be reserved, especially as the disease he described does not fit in with the usual picture of Friedländer pneumonia. Hyde and Hyde (1943) published 51 cases with a mortality-rate of 50%. They attributed their success to treatment with sulphonamide drugs and claimed that such treatment given early reduced the mortality-rate to 13%. Perlman and Bullowa (1941), who also used sulpha-drugs, had a mortality-rate of 84% in 37 cases.

Mortality-rates published before 1945 are as follows:

Reference	*No. of cases*	*Mortality-rate*
Zander (1919)	411 ..	30%
Cole (1928)	7 ..	71%
Bhatnagar and Singh (1935) ..	13 ..	92%
Solomon (1937)	32 ..	97%
Bullowa (1937)	30 ..	82%
Bullowa et al. (1937)	11 ..	83%
Perlman and Bullowa (1941) ..	37 ..	81%
Hyde and Hyde (1943)	51 ..	50%

STREPTOMYCIN

Experimental work by Heilman (1945) suggested that Friedländer pneumonia ought to respond to streptomycin. However, only a few cases thus treated have been published. Herrell and Nichols (1945) mention 2 cases of the bronchiectatic type treated successfully. Bishop and Rasmussen (1946) successfully treated an acute case after treatment with sulphadiazine and penicillin had failed. The National Research Council (1946), reporting on 17 cases treated with streptomycin, stated that "6 recovered permanently, 3 improved permanently, 3 improved temporarily, 3 showed no effect, and 1 died." This only adds up to 16 cases and no clinical details were given. Finland et al. (1946) published a case of bronchiectasis in which the Friedländer bacillus predominated in the sputum and disappeared under streptomycin therapy. Learner and Minnich (1946) and Keating (1948) each successfully treated 1 acute case with streptomycin. Harris et al. (1947) report 2 acute cases and 1 chronic case; in 1 of the acute cases the patient died soon after admission, but the 2 other patients recovered. Learner and Minnich's (1946) case had been treated with penicillin for six days before streptomycin was given. In the few cases in which penicillin was primarily used, it had little effect, except in 1 case reported by Kobacker and Mehlin (1945), who claimed a cure with penicillin. The streptomycin dosage in the various cases reported was 2–6 g. daily.

The following is a further case of acute Friedländer pneumonia treated with streptomycin.

A male chemical worker, aged 54, was admitted to the General Hospital, Nottingham, on March 6, 1949, with pneumonia. For some years he had had a cough and occasional mucoid sputum, which were worse in winter. Because of this he had been radiographed in January, 1949, but no abnormality was seen. Fourteen days before admission his cough and sputum had increased. Seven days before admission he had begun to feel ill, his sputum had become brown, and he had taken to his bed. He had since deteriorated, but had not had any pain. He had been troubled by dyspnœa for four days. He denied taking alcohol in excess.

On admission he was extremely ill with cyanosis, respiration 28 per min., temperature 100·4°F, and pulse-rate 108. His sputum was very viscid, stringy, and chocolate-coloured but not offensive. The only significant findings were in the chest. There was very little movement of the left hemithorax, and dullness was well-marked over the upper lobe, with bronchial breathing, whispering pectoriloquy, and some râles and crepitations. There were numerous adventitious sounds over the left lower lobe, and to a lesser degree over the whole of the right lung.

Treatment.—The patient was given continuous oxygen and was started on penicillin units 100,000 and sulphathiazole 1 g. three-hourly.

Investigations.—A white-cell count gave 11,200 per c.mm., with a normal differential count. His hæmoglobin was 84% (Haldane). The first specimen of sputum was unsatisfactory and showed a mixed flora. A further specimen taken the same day showed nearly all the organisms to be gram-negative capsulated rods, which on culture proved to be Friedländer bacilli. Other organisms were scanty and mainly pneumococci. The Friedländer bacilli were not typed. No blood-culture was taken. Radiography on the day after admission showed consolidation and early cavitation of the left upper lobe, with patchy consolidation in the remaining parts of the lungs (fig. 1).

Progress.—During the first few days in hospital the patient improved, but his sputum increased. He then started to deteriorate. Radiography on March 15 showed the pneum to have advanced, with multiple cavity formation in the lung and mediastinal shift to the right. On the same a white-c [illegible] .mm., but the differ count rer [illegible] hiazole was discontin in view of this count, and, in spite of the fact that sensitiv tests showed the Friedländer bacillus to be resistant penicillin, penicillin was increased to 1,000,000 units thre hourly. At this time the patient's temperature varied betw 99·6°F and 101°F; his pulse-rate was about 106, and resp tions constantly about 28 per min. On March 23 he coll and brought up considerable amounts of sputum contain much fresh blood. He remained in a very critical state for days and then improved slightly. Radiography on March showed a very large cavity in the left upper lobe and a sm cavity in the apex of the left lower lobe (fig. 2). The co solidation on the right side had resolved. A white cell co at this time gave 7600 per c.mm., with a normal differ count. He continued to lose an appreciable amount of bl in the sputum, and on April 3 his Hb was 40% (Hald He was given the cells from four pints of blood and one p of fresh blood (group A Rh-positive) in two days. Th raised the Hb to 70%. The white-cell count remained same.

Streptomycin Treatment.—On April 11 streptomycin bec available, and the Friedländer bacilli were shown to moderately sensitive to it. At this time the patient deteriorating slowly, losing weight, and very toxic. Postu drainage had had to be abandoned soon after being attempted The sputum continually grew almost pure cultures of Fried länder bacilli. The penicillin was discontinued, and a cour was started of streptomycin 1 g. twelve-hourly and sulph diazine 1 g. four-hourly. Within a few days the sputum bec free from blood and lost its chocolate colour, and the pati ceased to be toxic, and started to feel better. Within fe days it was possible to start postural drainage again, with goo effect. He started to put on flesh, and on April 16 a white-ce count gave 15,000 per c.mm., the highest since admission. Th improvement in Hb was maintained. Pulse-rate, respiration rate, and temperature became normal. To aid the drainage of the cavities he was bronchoscoped on April 22 (Mr. W. Buckley and Mr. E. J. G. Glass). Apart from injection of th left bronchial tree and pus in the main bronchi nothing of significance was seen. Serial radiography showed gradu diminution of the cavities, and on May 7 chemotherapy wa stopped, because the cavities contained no fluid (fig. 3 As long as the cavities contained fluid, Friendländer bacil persisted in the sputum, but pneumococci and *N. catarrhali* appeared in the sputum at the beginning of May. Furthe serial X-ray films showed the cavities becoming still smaller with mediastinal shift to the left. A film on July 7 showe residual damage in the left upper lobe. Clinical examinatio revealed very few crepitations and râles in the left upper zone with tracheal and mediastinal shift to the left. The scanty sputum contained mainly *N. catarrhalis.*

The present case was one of acute Friedländer pneu monia proceeding to cavitation. It was a typical cas

Streptomycin only became available after the diseas had been progressive for seven weeks, and it was for thi reason that alternative chemotherapy was first tried During this time the consolidation in the right lun resolved, while the lesion in the left lung progressed The lesions in the right lung were earlier lesions, and i this connexion the reports of Hyde and Hyde (1943 and Kobacker and Mehlin (1945) are of interest Possibly the patient might have survived without th help of streptomycin, but the clinical effect was dramati and altered the whole course of the pneumonia. O interest is the clearing of the leucopenia soon afte streptomycin therapy was started.

SUMMARY

A typical case of primary Friedländer pneumonia refractory to penicillin and sulphonamide, responde dramatically to streptomycin.

I wish to thank Dr. W. S. Whimster, under whose car this case was, for the help and encouragement he ha given me.

n the work reported here estimations of the histamine tent and tests for histaminase activity were made ultaneously on the blood and serum of 121 women with mal and toxæmic pregnancy in various stages of tation. Since the results suggested that in some ditions of pregnancy histamine might shift from the cells into the tissue fluids, it was decided to estimate separately the histamine content in the plasma and in the blood-cells of women with normal and toxæmic pregnancy.

METHODS

Simultaneous Estimations of Histamine in Plasma and Blood-cells.—10 ml. of citrated blood was centrifuged at 3000 r.p.m. for fifteen minutes. Only specimens completely free from hæmolysis were tested. The plasma was very carefully separated from the blood-cells, and the histamine content of both plasma and blood-cells was separately determined by Code's (1937) modification of the biological method of Barsoum and Gaddum (1935). In every case histamine was identified by tests with the anti-histamine drug 'Neoantergan' by the quantitative method described by Reuse (1948). The results were expressed as microgrammes of histamine per litre of blood.

Test for Serum-histaminase.—A modification of the colorimetric indigo-disulphonate method of Zeller et al. (1941b) was used.

Add to 1 ml. of serum 2·5 ml. of $M/15$ phosphate buffer (Sörensen) with pH 7·2, 0·1 ml. of a histamine solution in $M/15$ phosphate buffer containing 1 mg. of histamine hydrochloride, 0·4 ml. of a solution of 20 mg. of indigo disulphonate in 30 ml. $M/15$ phosphate buffer, and one drop of N-octyl-alcohol. Shake well and pass oxygen through the solution for one minute. Close the test-tube with a rubber stopper and incubate for twenty-four hours at 37°C.

Each serum is tested in triplicate, and a control estimation is always done without histamine. After incubation the initial blue colour of the control usually does not change.

The histaminase activity of the serum is estimated from the colour, +++ indicating that decoloration is complete, ++ distinct, + weak, ± very faint, and 0 absent.

RESULTS

The results obtained in 91 pregnant women in various stages and conditions of pregnancy and 8 non-pregnant women are shown in tables I–VIII.

In the 8 *non-pregnant women* (table I) no histaminase was detected in the serum. No histamine was found in the plasma, except for small amounts in 4 cases.

In 25 cases of *normal pregnancy* (table II) the highest serum-histaminase levels were found between the seventh and eighth months. In only 7 cases was hista-

mine found in the plasma in small amounts. Marcou and Athanasiu-Vergu (1937) also obtained only a trace of histamine in the plasma of pregnant women.

Of 16 cases of *mild pre-eclamptic toxæmia* (table III) a few showed a slightly diminished enzymic activity. In many, however, higher plasma-histamine levels were found than in normal pregnancy. Measurable amounts of histamine were present in the plasma in 12 of these 16 cases. This number is significantly greater than the number for normal pregnancy ($P < 0{\cdot}01$). The mean cell-histamine level did not significantly differ from that of normal pregnancy.

The activity of serum-histaminase was distinctly decreased in the 16 cases of moderate or severe *pre-eclamptic toxæmia* (table IV). In all these cases measurable amounts of histamine were present in the plasma. There can be no doubt ($P < 0{\cdot}001$) that this result shows that measurable amounts of histamine were found in the plasma with significantly greater frequency among these cases than in normal pregnancy. The histamine content of the blood-cells was remarkably low in all cases but 1, and the mean value was significantly lower than in normal pregnancy ($P < 0{\cdot}01$). In many cases the histamine content of the plasma exceeded that of the blood-cells. Case 60, with a very high plasma-histamine level and an exceedingly low blood-cell histamine level, had extremely severe pre-eclamptic toxæmia.

All but 3 of the 15 women in various stages of *labour* (table V) showed a rise in the plasma-histamine compared with normal pregnant women before term. 12 women had measurable amounts of histamine in their plasma. This number of cases is significantly greater than the result for normal pregnancy ($P < 0{\cdot}02$). In some cases the plasma-histamine was higher than the blood-cell histamine. Case 77 was a woman with pre-eclamptic toxæmia in the second stage of labour, and case 77a was the same woman in the third stage, when histamine had almost completely disappeared from the blood-cells and only little histamine was detectable in the plasma. Marcou and Athanasiu-Vergu (1937) also found a raised plasma-histamine during labour.

TABLE IV—FINDINGS IN MODERATE AND SEVERE PRE-ECLAMPTIC TOXÆMIA

Case no.	Weeks of gestation	Serum-histaminase	Histamine (µg. per litre of blood)	
			In blood-cells	In plasma
50	26	± to +	15	10

Mean	..	..	20·9 ±4·2	..

As regards histaminase, 4 of 15 women showed normal activity in the serum, whereas in the rest the serum-histaminase level had more or less fallen. Cases [illegible] and 76, with a high histaminase activity, were both cases of toxæmic pregnancy in the first stage of labour with very protracted primary uterine inertia.

Only a faint histaminase activity was detected in the sera of 3 out of 9 *puerperal patients* (table VI). The plasma of these women generally did not contain any detectable histamine. The 3 women whose plasma contained histamine were case 81, an eclamptic women who delivered herself of a thirty weeks' fœtus, case 82, who had mild toxæmic pregnancy, and case 85, who had severe toxæmia of pregnancy after a twin pregnancy and stillbirths. Case 84 was delivered of a baby with acute icterus neonatorum.

A definite rise in the plasma-histamine level in 4 out of 5 cases of *pyelitis of pregnancy* (table VII) suggests a toxæmic origin of this condition in pregnancy. No spectacular change was seen in the activity of serum-histaminase as compared with that in normal pregnancy.

Cases 95–98 (table VIII) were threatened abortions. Histaminase activity was hardly detectable in the serum. Of the 4 cases, 3 showed considerable amounts of histamine in the plasma. Case 99, antepartum hæmorrhage, showed normal histaminase activity but a raised plasma-histamine level.

DISCUSSION

The considerable increase of plasma-histamine in toxæmic pregnancy and in labour can be explained on the hypothesis that the histamine metabolism in pregnancy differs from that in non-pregnant women in that, in pregnancy, histamine can easily shift from the cells into the tissue fluids. This suggestion seems to be borne out by the increase in serum-histaminase prevailing throughout normal pregnancy. This significant increase may be regarded as a protection against potential intoxication with histamine. In severe cases of toxæmic pregnancy a highly decreased or completely absent activity of the serum-histaminase seems to be always associated with a comparatively low histamine content of the blood-cells and a somewhat higher plasma-histamine. Perhaps in these circumstances histamine, not metabolised by histaminase, is extravasated into the surrounding tissue and thus begins to exert its toxic ts. The observation that in labour the plasma ains considerable amounts of histamine suggests histamine may play a part during parturition.

ne observation that in a few cases of threatened tion histamine was present in the plasma and uminase was hardly detectable in the serum may also ignificant.

nce it is generally accepted that histaminase is luced in the placenta (Danforth and Gosham 1937. con et al. 1938. Zeller et al. 1939, Ahlmark 1944, eller-Adler 1944. Swanberg 1948), any degenerative nges in the placenta may be responsible for a inished or absent activity of the serum-histaminase regnancy.

erhaps the increase of histamine in pregnancy is to the peculiar histidine metabolism prevailing uring gestation. Histamine might be formed in pregancy from histidine through the activity of the enzyme stidine decarboxylase. whose occurrence in man, wever. still remains to be proved.

SUMMARY

The histamine content was separately estimated in the lasma and in the blood-cells of pregnant women in arious stages and conditions of pregnancy. Histaminase tivity was simultaneously determined in the serum of ese women by a modification of the indigo-disulphonate action of Zeller et al. (1941b).

Strong histaminase activity was found in the serum f all the pregnant women. Histamine was present in he blood-cells in amounts comparable with those found the blood of non-pregnant women. It was hardly etectable in the plasma.

In mild toxæmia of pregnancy the histaminase activity id not differ much from that in normal pregnancy. Higher values. however, than in normal pregnancy were btained for plasma-histamine. In severe toxæmia f pregnancy the histaminase activity was distinctly ecreased. The histamine level in the blood-cells was emarkably low, being in many cases exceeded by the level n the plasma, which was high.

Considerable amounts of histamine were found in the lasma of women in labour. Histaminase activity seemed to decline in the later stages of labour.

WITHDRAWAL SYMPTOMS IN CANNABIS-INDICA ADDICTS

J. D. FRASER
M.D. Glasg., D.P.M.
DEPUTY MEDICAL SUPERINTENDENT, WHITTINGHAM HOSPITAL, LANCASHIRE; LATE MAJOR, R.A.M.C.

DURING the early days of a campaign in the Far East, several cases of an acute psychosis associated with the withdrawal of cannabis indica from addicts came to my notice. All these cases came in the first four weeks of the campaign and all were in Indian troops.

Hemp grows readily in certain parts of India and in such parts is easy to obtain. As an intoxicant, for smoking and chewing, it is made in the three forms of bhang, ganja, and charas.

1. *Bhang* consists of the dried leaves and small stalks of the hemp: a few fruits occur in it. It is of a dark brownish-green colour, and has a faint peculiar odour and but a slight taste. It is smoked with or without tobacco or it is made into a sweetmeat with honey, sugar, and aromatic spices: or it is powdered and infused in cold water, yielding a turbid drink.
2. *Ganja* consists of the flowering and fruiting heads of the female plant. It is brownish-green, and otherwise resembles bhang, as in odour and taste.
3. *Charas* is the resin itself collected, as it exudes from the plant.

Altogether 9 cases came to my notice, and all gave a similar history and presented similar signs. All had been indulging in ganja smoking for some years and they soon began to notice signs of deprivation when they left India; 2 showed signs of extreme irritability on the sea voyage but got over this when they managed to procure some more ganja from their comrades. On arrival at their destination all began to suffer from deprivation; the Indian hemp plant did not grow so widely, and ganja became difficult to obtain.

Each case was known to his comrades as a ganja addict; he was regarded with a certain amount of fear, and was known to be untrustworthy. Irritability increased and culminated in a sudden outburst of violence, such as stabbing another man, striking out, or shooting at someone. A common history was that the man had been on guard duty and had suddenly begun to blaze away with his rifle or Sten gun at an imaginary enemy. This sort of conduct resulted in the man being brought under medical observation; and the strange, and often dangerous, fact was that by the time he got back to a medical unit he had become quiet and apparently rational. During this quiet phase, the man seemed mildly depressed but was appreciative of attention; he took his food and enjoyed a smoke. Patients have been returned to their units during this quiet phase with disastrous results. After 48–72 hours there was another outburst of impulsive violence, followed by an acute psychotic episode lasting 3–6 weeks. This phase was characterised by acute excitement; the patients shouted and talked at great length, interfered with other patients, and were very quarrelsome. They stripped themselves of all clothing and masturbated almost continuously; their habits became filthy, fæces and urine being passed in the bed or on the floor. Some would sing at the top of their voices for hours. On seeing a nursing orderly or a medical officer they would crawl abjectly along the floor and beg for some ganja. If offered an ordinary cigarette they would snatch it from one's hand and chew it up or smoke it as quickly as possible. At times, most of the patients appeared to be both visually and aurally hallucinated and the hallucinations were terrifying. They could understand what was said to them and would start to obey an order, but their attention would flag quickly and they would again start to beg for more ganja. If unsupervised they would fight amongst themselves for a cigarette end. Some cases ate their food in a voracious manner whilst others refused both food and water.

All these cases were treated by sedation with either *soluble barbitone or paraldehyde, which were the only* sedatives available; they were also given ordinary cigarettes. Continuous narcosis was first aimed at, but in 2 cases an intercurrent infection—pneumonia in one and malaria in the other—developed while the patients were deeply sedated; so the other cases were not given so much sedative.

None of the 9 patients died, which surprised me; and all emerged from the psychotic phase after a period of 3–5 weeks; they then became quiet, coöperative, and well-conducted, though all were weak and emaciated, and required considerable feeding up. All were evacuated to India.

DISCUSSION

It is clear that some cannabis-indica addicts cannot manage without the drug; when deprived of it they develop a dangerous mental illness. It seemed that the proportion of addicts who developed this illness was comparatively small; certainly there were far more than 9 ganja addicts in Indian units served by the medical unit at which I was stationed. All 9 men smoked ganja continuously when at home in India, and all were of average intelligence; they came from various units—some high-grade, others pioneer units.

Clearly it would be safer if known cannabis-indica addicts were not employed on foreign service.

Preliminary Communication

ACUTE LARYNGOTRACHEOBRONCHITIS TREATED WITH CHLOROMYCETIN

Laryngo-tracheo-bronchitis is one of the most alarmi emergencies with which the children's physician has deal. Other acute affections of the respiratory tr usually appear to yield to chemotherapy; but this c like atypical pneumonia, has apparently been uninfluenc by such treatment. There is some evidence that it caused by a virus.

Attacking children between six months and th years of age, with a sudden onset, the infection le rapidly to a critical state, often necessitating tracheoto and bronchoscopic suction. Of six children, all enough to require surgical intervention, treated at Hospital for Sick Children, Great Ormond Street, si December, 1947, four died. On the admission of seventh case Dr. I. A. B. Cathie suggested the trial 'Chloromycetin,' and the result seemed to be drama Though one of the youngest of the small series certainly the youngest to survive, this child's st changed rapidly from one of extreme seriousness to of easy convalescence. All other adjuvant measu were used: the child was nursed in an oxygen tent w "special" nurses; tracheotomy was performed suction carried out as required. Chloramphen (chloromycetin) was given by mouth in 0·25 g. d three times a day for four days, starting a few ho after the tracheotomy. The thick, tenacious secret found at tracheotomy in these cases became thin less profuse than in other cases. Bronchoscopy was o required once, the temperature reached normal in hours, and the tracheotomy tube was removed wit five days.

Details of the seven cases are:

Case	*Age*	*Duration of severely obstructed breathing before tracheotomy*	*Resu*
1	1 year 1 month	24 hours	Die
2	2 years	3 hours	Liv
3	*10 months*	*12 hours*	Die
4	9 months	30 hours	Die
5	2 years 11 months	1 hour	Liv
6	1 year	36 hours	Die
7	1 year 3 months	12 hours	Liv

It will be noted that the children who survived w those in whom tracheotomy was performed early, chloramphenicol must not be regarded as a substit *for mechanical relief of obstruction at an early st* when required.

This preliminary note is intended to encourage oth to try this new drug for a disease with an unfortunat high fatality-rate. It is unlikely always to obviate necessity for the skilled assistance of surgical colleag but it may shorten the whole period of illness and ren the infection less virulent.

". . . Consider medical salaries: a psychiatrist in prison service has a salary scale of £1000–£1400 a y A similarly qualified officer in the National Health Ser is on a scale of £1700 (linked to age 32) rising . . . to a ma mum, reached in eight years, of £2750. Does this mean t salaries are fixed on a catch as catch can basis? *Or t* the Government have decided they do not want psychiatr in the prison service but lack courage to announce *the fa* Or . . . that it is Government policy to reduce the medi Civil Service to a cipher? *One can illustrate this lack* any clearly conceived policy at any and every level.' —Mr. Stanley Mayne, general secretary of the Institut of Professional Civil Servants, in a letter to the *Tim* Oct. 18.

Medical Societies

ROYAL SOCIETY OF MEDICINE

Rheumatoid Arthritis

MEETING of the section of physical medicine on 12, with Dr. HUGH BURT, the president. in the chair, devoted to the effects of treatment with 'Cortisone' adrenocorticotropic hormone. Dr. Burt emphasised importance of the discovery of cortisone not only he study of arthritis but also for general medicine.

T. OSWALD SAVAGE, anticipating the question oes cortisone work?" replied with an emphatic mative, and described the two patients suffering from matoid arthritis whom he had seen before and after atment. He then sketched the history of the discovery ortisone. reminding his audience that rumours of the ct of suprarenal cortical extracts on soldiers and ts suffering from battle fatigue had drawn attention these substances. He recalled Hench's prolonged dy of rheumatoid arthritis and the fact that this rker had recently discarded the microbic theory of ology and had emphasised the potential reversibility rheumatoid arthritis. postulating in 1948 that there ist be an "antirheumatic factor *x*" potentially pable of reversing the effects of the disease. Hench d concluded that some such substance might exist the suprarenal cortex and had consulted Kendall on is subject. While there were at least 28 suprarenal roids, only 6 of these were known to be active, and in eumatoid arthritis it was the 11-oxysteroids that were portant. These acted on carbohydrate metabolism, using a rise in liver glycogen content and an increased ea excretion. The pituitary adrenocorticotropic horone (A.C.T.H.) caused an increased secretion of supranal steroids. In 1940 Kendall had isolated cortisone, 17-hydroxy-11-dehydrocorticosterone, and had called Compound E. It was this compound that Hench ecided to investigate in rheumatoid arthritis. After s intramuscular injection in adequate amounts patients nickly lost their tenderness, pain. and stiffness, and eveloped a remarkable euphoria and ravenous appetite. r. Savage showed slides provided by Hench which lustrated the improvement. He went on to say that he increased sedimentation-rate and lowered hæmolobin of rheumatoid arthritics responded well to ortisone therapy though not so instantaneously as the linical condition. It seemed that for cortisone therapy daily injection of 100 mg. was necessary, while for .C.T.H. 25 mg. had to be given three times a day.

The side-effects of cortisone therapy would have to e carefully studied. Obesity. hirsuties, amenorrhœa, nd depression had all been noticed. So far as was known. cortisone therapy had to be continued indefinitely, for patients had all relapsed when injections were stopped. On the other hand only severely affected patients had so far been treated. Cortisone was an extremely scarce and expensive drug which at present was synthesised from desoxycholic acid by a process involving 39 difficult chemical steps. In Dr. Savage's opinion the significance of the discovery was that it had shown that rheumatoid arthritis could be reversed by drug therapy and that it was a yardstick by which to estimate the value of other forms of treatment.

Dr. RAYMOND GREENE pointed out that there had been much study for many years on the relation between the suprarenal cortex and arthritis. Selye in 1944 had shown that desoxycorticosterone, when administered under certain conditions, could cause arthritis, and in 1946 had described his "adaptation syndrome" which possibly inspired Hench. Dr. Greene himself had studied the exciting causes of rheumatoid arthritis for a long time and had concluded that the hypothalamus and suprarenal cortex might play a related part in its ætiology. This had led him to treat patients with 'Eucortone' and pituitary adrenocorticotropic hormone, but he had found that whole suprarenal cortex was ineffective. He described how. in 1946, he treated a desperately ill rheumatoid arthritic. who also suffered from pemphigus, with intravenous procaine, following Ungar's suggestion that this stimulated the suprarenals. Subsequently A.C.T.H. and procaine were given and the patient made steady progress with occasional relapses. Later the patient developed jaundice. which again improved his arthritis and his rash. He was now apparently cured, showing only residual deformities of the hands. Dr. Greene then introduced this patient to the audience as the first patient who had been treated for rheumatoid arthritis with corticotropin. He was now, he said, testing substances having an inhibitory effect on histamine production. He had had some success with large doses of intravenous procaine, which possibly worked through the suprarenals. He then recalled the work done by Bach and Savage on splenectomy for rheumatoid arthritis and reminded the audience that Ungar had found splenin A in the blood of normal controls but splenin B in the blood of rheumatoid arthritics. He had confirmed the finding of splenin B in active rheumatoid arthritis and he called for further study of the rôle of the spleen in the disease.

In the subsequent discussion Dr. M. GOOD described long-continued cortisone therapy as very dangerous. He said that he had worked out a perfectly satisfactory method of curing rheumatoid arthritis at any stage by injecting myalgic spots with small doses of procaine. Dr. FRANCIS BACH regarded the work on cortisone as a valuable investigation rather than, as yet. a form of treatment. He suggested that the time would come when the part played by the thyroid, the spleen. and the suprarenals could be correlated in a scientific manner.

Reviews of Books

Textbook of Surgery

PATRICK KIELY, B.SC.. M.CH.. F.R.C.S., professor of surgery, University College, Cork. London: H. K. Lewis. 1949. Pp. 1184. 45s.

THIS is a textbook of general surgery written by a single author because to "the student the whole subject of surgery must be presented in a general way and must be reasonably balanced." In this sentence Professor Kiely gives us a strong argument for the single-author book. This. at all events. is a work of admirable balance, in which the statements about disease are obviously based on observation and experience and so have the imprint of truth. It has no special chapters on bacteriology and immunology, referring to these subjects only in connexion with special surgical conditions. The teaching is similar to that in English textbooks, but a few points may be criticised. Penicillin has so greatly revolutionised our ideas about septic infections that Professor Kiely might have referred more prominently to its use. For instance, large incisions for whitlows are no longer necessary. and particular objections can be raised to the "fish.mouth" incision recommended. Though extremely practical, he is rather superficial in his descriptions of diseases: nobody could acquire. from his account. any definite views about the pathology of the enlarged prostate or of chronic mastitis—or even get mildly interested in them from that point of view. Lane's and Brophy's operations for cleft-palate are never done in this country; and the prolapsed intervertebral disc is very seldom approached transdurally. but the recommendation to divide the affected dorsal root. if it can be distinguished. is sound. Modern operations for carcinoma of the œsophagus and for cardiospasm do not seem to be described. These small points and a few others could be easily remedied in subsequent editions. In general the book is reliable. and gives the mature judgment of an experienced and intrepid surgeon.

Textbook of Bacteriology

C. H. BROWNING, M.D., F.R.S., Gardiner professor of bacteriology, University of Glasgow; T. J. MACKIE, M.D., professor of bacteriology, University of Edinburgh. London: Oxford University Press. 1949. Pp. 907. 50*s*.

FOR forty years medical students read Muir and Ritchie's handbook, but progress in bacteriology has been so rapid that the 1937 edition has been losing its place on the shelf. Now it reappears in handsome and enlarged format—a comprehensive textbook on protozoa and fungi as well as on the bacteria and viruses which attack man. It has been almost entirely rewritten and now includes an account of most recent advances on the subject. It will be read more by the advanced student and bench worker than its predecessor was, and less by the man who wants to know what is wrong and how to treat his patient. The accounts of individual bacteria are accurate though often discursive, and in the virus section compression has not always made for clarity. The chapter on fungi by Dr. Cranston Low is a good account of essentials, and the protozoa are also clearly described. The handbook always had excellent black-and-white illustrations, and many of the new ones maintain the standard. There is a valuable bibliography: but a few subjects, such as bacteriophage, have some references of parochial rather than of general interest. In its fifty-second year the book takes a new lease of useful life.

Testing School Children

WILLIAM STEPHENSON, M.A., M.SC., PH.D., fellow of the British Psychological Society, sometime reader in experimental psychology, University of Oxford. London: *Longmans, Green. 1949. Pp. 125. 12s. 6d.*

Dr. Stephenson is convinced, as are many others, that great danger lies in too hard and fast a selection of children at eleven years for placing in the different kinds of secondary school.

He would like to see something nearer the American style of a single-type secondary school, followed by university education for all who wish it. He is a self-confessed admirer of American education, but he vigorously trounces some of the results. Nor is he blind to the fact that a higher degree of standardisation in schools would inevitably lead at first to a levelling down. This admission is in arresting contrast to several remarks in the book, where his admiration of good preparatory and public-school education seems to have almost a snob value. Nevertheless, his hot-headed tilting at present-day selection for schools should keep us from any complacent notion that the Education Act, 1944, now provides an equal opportunity for all.

His chief contention is that eleven is far too young an age for children to be separated into several streams; it enforces fantastically early specialisation, and thus robs them of "[illegible] ucation which we hoped to ensure by [illegible] Certificate examination and instituting record cards.

Next he sounds a warning note about the indiscriminate use of intelligence tests, particularly by untrained workers, who, he suggests, apply a test (often any test), with a view to reading off the I.Q. much as one would read off the temperature on a thermometer. In a simple, even rather sketchy, way he explains that "intelligence" has many facets, and that tests chosen to discriminate between some of the different factors can also be used to tell us a great deal about the children tested.

Modern selection methods, as everybody knows, are not needed to pick the tops and the bottoms; anyone can do that. But *in skilled hands* they can be valuable in revealing latent capacity in the apparently mediocre, and thinness of quality or superficiality in the apparently first-rate. In an appendix Dr. Stephenson gives tests which he considers suitable for applying to eleven-year-olds; but since he deliberately omits any reference to norms and standards of scoring, they only stimulate thought as to what a test really tests.

His are arranged so as to occupy a whole day, and test mainly the G-factor (general intelligence), verbal facility (V-factor), and kinæsthetic ability (K-factor). The last are interspersed with some arithmetical tests. He ends with a poetry-completion test which he considers calls for originality in thought, as well as skill in manipulating word imagination and feeling combined. An inhibited c thinks, lacks the capacity to gratify his felt needs, a will result in a lack of creative imagination, brought this test.

The practical value of such a scheme of testing be judged without much further information; scheme as a whole is challenging and arresting, a book will take both child and tester into a stim mental atmosphere. The appendix incidentall contains a brief account of the Rorschach test to the author acknowledges his debt.

Die Insulin-Lipodystrophie

DR. FERDINAND ADALBERT KEHRER, director of psychiatry clinic, University of Münster. St Thieme. 1949. Pp. 50. DM. 4.50.

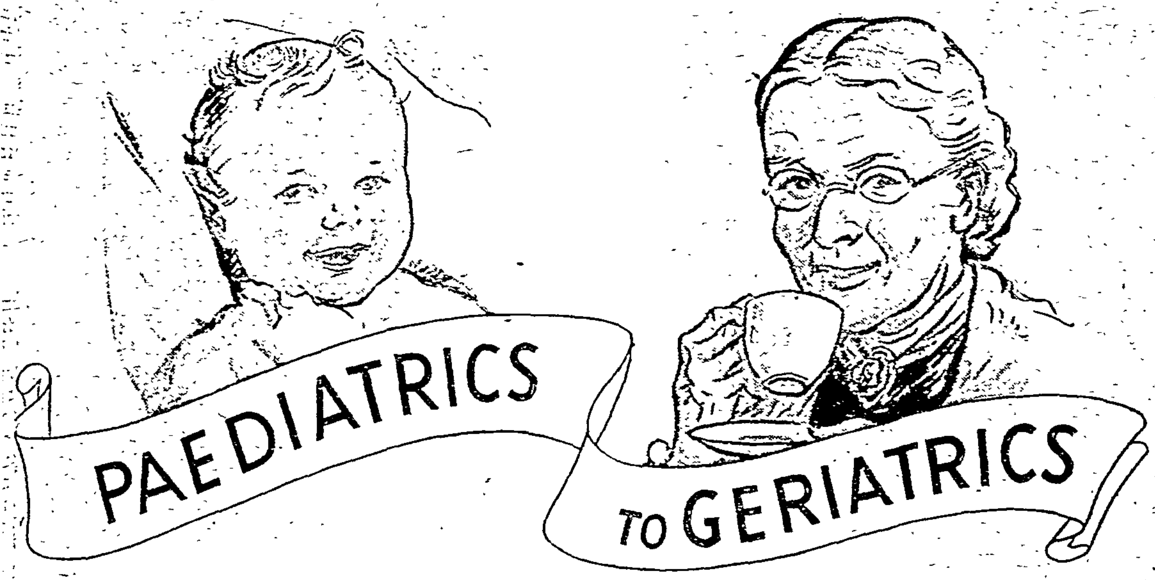
THIS small book describes most of the aspects mysterious disappearance of fat not uncommonl at and near the site of insulin injections after mo years of treatment. It confirms the well-known fa it occurs mostly in women and children, and onl rarely in men. A sifting of the literature, almost German, leads to no explanation of the funda pathological or ætiological factors and no useful sugg about treatment.

Medical Annual 1949 (67th year. Bristol: John W Sons. 1949. Pp. 448. 25*s*.).—A strong following stand un editorial banners of Sir Henry Tidy and Prof. A. Short, who here renew their annual campaign to kee to date. As usual the introduction gives promin subjects of special interest, and the subsequent pa packed with well-informed articles, alphabetically a and helpfully illustrated.

Principles of Human Physiology (10th ed. L J. & A. Churchill. 1949. Pp. 1193. 42*s*.).—Good boo no puff. Most medical students become familia "Starling," in their second year, and the intimacy is through life. Prof. Lovatt Evans's latest version of the is slightly larger than the last, thanks to new matt 60 new figures. The duty of the author of a textb remarks in his preface, is "to select such exam represent, in his opinion, either current trends o established advances." He leaves to his reade fascinating task of identifying new features in this editi

Synopsis of Medicine (9th ed. Bristol: John Wr Sons. 1949. Pp. 1243. 30*s*.).—Sir Henry Tidy's synop become so well known a standby to both students and that little need be said about this new edition, the ninth first appeared in 1920. A synopsis, according to the dict means "a collective or general view of a subject." fully true of Tidy's book, which has become a compre and almost indispensable work of reference. The new includes for the first time temporal arteritis, acute necrosis of the kidney, and the influence of maternal on congenital defects. Many new paragraphs have been and it is surprising how little has been omitted in the field of clinical medicine. In spite of new matter t has been only slightly increased.

Hematology for Students and Practitioners (2 London: Hamish Hamilton Medical Books. 1949. P +viii. 44*s*.).—This volume by Prof. Willis M. Fowler o is reasonably long, well produced, and well illustrated various blood diseases are dealt with succinctly, but frills are allowed and the telegraphic style happily is a Each chapter ends with a useful list of key references, is pleasant indeed to see British workers, properly sented. Unfortunately, Professor Fowler still adhe views about the development of erythroblasts and er cytes in health and disease which have been discarded country for some years. He does this quite deliberatel states his reasons. But this means that his textbook be recommended to students or practitioners in this co since they will have to go elsewhere for a description anæmias which will correspond to that of their teachers these have reasons for their views at least as good as Pro Fowler's. The illustrations are inadequate, and even— erythroblasts are concerned—positively misleading. T a pity because there is an opening for a book of this le though at a more moderate price.



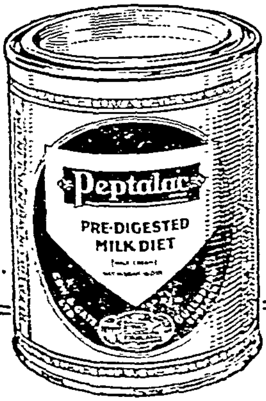
Peptalac

REGD

PRE-DIGESTED MILK FOOD

FORMULA	
FAT	1.8%
PROTEIN	2.4%
PREDIGESTED PROTEIN	0.8%
LACTOSE	4.1%
DEXTRINIZED STARCH	2.4%
MINERAL SALTS	0.8%

PEPTALAC, a predigested milk dietary, has been invaluable in the treatment of dietetic upsets, both of the young child, the adult, and the aged.
It is most palatable and is used as a dietary supplement in those suffering or convalescing from winter ills, gastric or duodenal ulcer, gastro intestinal upset and in the gastric ailments associated with old age.
PEPTALAC contains predigested protein of which a definite amount has been pancreatised to form amino acids and peptones.
PEPTALAC also contains dextrinized starch which allows of easy assimilation.
PEPTALAC is readily prepared by the addition of hot water.
PEPTALAC is a Cow & Gate Standardised Product.



COW & GATE LTD. GUILDFORD, ENGLAND

'An extremely potent oral œstrogen'

At the time of the menopause many women suffer from distressing subjective symptoms which are due to endocrine imbalance caused by failing ovarian function. Prompt relief may be obtained by the judicious administration of a potent, well-tolerated œstrogen.

Ethinyl œstradiol is eminently suitable for such a purpose. It is the most active œstrogenic substance known, is effective orally and, since it is a simple derivative of the natural ovarian hormone, is less likely than the synthetic œstrogens to cause unpleasant side-reactions. Further, ethinyl œstradiol (available as 'Estigyn') has a predominantly pituitary-inhibiting action, which renders it particularly effective in relieving the disturbances of the menopause.

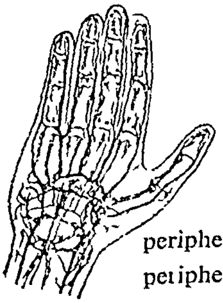
in Circulatory Dysfunction



'PADUTIN', an extract from the pancreas, has a selective action on peripheral circulation. Administration of this hormone produces dilatation of the peripheral blood vessels, with increased blood flow, limb volume and surface temperature. There is no appreciable effect on the blood pressure.

'Padutin' is of benefit in intermittent claudication, Raynaud's and Buerger's disease, and in faulty circulation giving rise to acrocyanosis and chilblains. Among the packings listed below the 10 ml. bottle will be found particularly convenient.

'PADUTIN' *Trade Mark*

Ampoules (10 biological units per ml.)
Boxes of 5 and 50 × 1 ml.
Oral Solution (10 biological units per ml.)
Bottles of 10 and 50 ml.

The Distinction Awards

NEW ideas, whether good or bad, have a precarious : a hundred and one reasons can always be found killing them off. The Spens Committee produced a w idea for countering the deadening effect, in a national vice, of payment according to rank and seniority.

> "We are satisfied," they said, "that there is a far greater diversity of ability and effort among specialists han admits of remuneration by some simple scale pplicable to all. If the recruitment and status of specialist practice are to be maintained, specialists must e able to feel that more than ordinary ability and effort receive an adequate reward. Moreover, a reward which would be appropriate when these exist would be extravagant when they do not. In consequence we are clear that any satisfactory system of remuneration must involve differentiation dependent on professional distinction."[1]

his led to the proposal that after a specialist had ached his maximum basic salary of £2500 (now 750), his remuneration should cease to depend in ay way on the length of his service, but that distinc-on awards, of three different grades, should be made 34% of specialists selected (by a mainly professional dy) as exceptionally meritorious. On this basis, nd not otherwise, the committee persuaded a reluc-nt Treasury that doctors in the National Health ervice should be able to earn well over £5000 a year ithout private practice. A Socialist Government ay well have felt that £2750—which was rather more han previous professorial salaries—was an adequate alary for consultants; but it was induced to add ell over another million pounds by the argument hat particularly good work should bring financial dvantage.

In due course a Distinction Awards Committee was ppointed, with Lord MORAN as chairman. Obviously ts members could not possibly know all the thousands f possible candidates for these awards, and they have herefore begun by asking help from people who do know them—from the medical committees of teaching hospitals, from the assessment committees of regions, and from the Royal Colleges and specialist associations. It is at this point, when consultants find themselves (as they feel) reducing some of their friends' incomes, that the new idea reaches its greatest danger; for those who rejected it from the first are joined by those who find its application difficult and distasteful. The difficulty and distastefulness are real enough: and what could seem more convincing than Dr. WALSHE's condemnation of the whole business?

> "It is one thing to grade a series of posts but quite another to seek to grade professional distinction, and it passes my comprehension that anyone who has spent his working life in medicine—unless as an administrator—could suppose that a grading of this order can be rationally and equitably accomplished. . . . What constitutes 'distinction' in medicine? Is it aptitude in the variegated arts of worldly success? Is it clinical wisdom, therapeutic fervour, or the acceptable usage of the forms of sickroom politeness? Is it the gift of training students or fruitfulness in original research? Is it the acquisition of seniority by lapse of years or a flair for planning the activities of one's colleagues? Is it to be a Mary or a Martha in medicine? How are these incommensurables, these diverse qualities of mind, heart, and worldly wisdom, to be comparatively assessed in terms of sterling?"[2]

But Dr. WALSHE, unlike the Spens Committee, is not setting his mind to the solution of a practical problem. He may be right in saying that the value of various professional attributes cannot be compared; yet it is still true that a man's colleagues generally have an opinion on whether he is doing especially good work or in some way making a contribution beyond the ordinary. To be asked to say which of one's associates is outstanding, and if so to what degree, need not seem outrageous if one remembers that we are all assessing other people all day long. The patient assesses the practitioner; the practitioner assesses the consultant; and the consultant assesses the candidates whenever he helps to choose a houseman or a registrar or a new member of the staff—all of which assessments have financial implications. To assess a colleague for an award is more uncomfortable in one way, because he is a colleague; but it is less uncomfortable in another way, because the assessment will not be decisive but is merely part of the evidence on which a central committee, with its own policy, will compile the final list. The more the responsibility is spread between different advisers, the less need anyone feel that he has let his associates down or has been let down by them. There are bound to be mistakes, if only because the merit of doctors, like the merit of poets and artists, is not quite always apparent to those around them, and because dividing lines are tenuous, to say the least. Also, as in the nursery, at school, in the Army, in the Honours List, and even in the learned societies, there will be an element of luck in the distribution of the rewards. Perhaps the wisest attitude for the possible recipient is to recognise the contest as one in which nobody loses though some can win: he should neither count on a prize nor feel deprived if it does not come his way.

At the same time the scheme stands or falls by whether, broadly speaking, the awards are the right ones: and this brings us to the question of its possible abandonment or modification if instead of standing it is found to fall. There are those who think it fundamentally unstable; and without a trial we cannot prove them wrong. There are those who would confine it to whole-time members of the service, leaving the part-timers to draw their supplementary incomes from private practice. There are those who believe it could only be made tolerable by removing the element of personal judgment and substituting a points system by which distinction would be estimated objectively. There are some who would like the awards kept private, and many who favour smaller changes in the present arrangements. It would indeed be strange if so important a scheme, which may prove a major precedent in the organisation of other national services, were free from defects at its inception; and in reaffirming our own faith in it we must admit that the only convincing test is experience. Since in fact a considerable number of consultants are assisting the Distinction Awards Committee against what they believe to be their better judgment, and others have refused to assist at all, might it not be best to meet the objectors and the doubters by declaring that the scheme is experimental—by setting a term of perhaps five years to the awards now made, after which consultants as a body could themselves decide whether it be discontinued or altered? If this novel system of remuneration were introduced in the form of a terminable trial rather than as an irremovable feature of the new service, it might be more acceptable to the minority who are not yet convinced that it is sound.

---

[1] Remuneration of Consultants and Specialists. Cmd. 7420. H.M. Stationery Office, 1948; p. 10.

[2] Walshe, F. M. R. *Brit. med. J.* Aug. 13, p. 353.

On the other hand we have no doubt that the system, experimental or not, should now be introduced, and we believe the majority of consultants to be of the same opinion. The mechanism by which, under the old order, special merit was specially rewarded has largely broken down in the National Health Service, and it needs to be redesigned in one way or another. We share the view of Dr. BURNS[3] that the kind of distinction that ought to be recognised is "distinction in professional service to the community," and we hold that the profession is on the whole capable of assessing such service more justly than the laity. Of course, general practitioners and patients will be foolish if they suppose—as some of them will—that a consultant is necessarily less suitable for their purpose because he has no award or because it is not the highest: every wise man should know that rank of any kind is but the guinea stamp. But what Dr. WALSHE derisively terms "a first, a second, or a third class 'distinction' label issued from Whitehall" should at worst be no more misleading than the title, the car, the clothes, and the address, by which the standing of the specialist has too often been judged in the past. And to accept at this stage the alternative of standard salaries would be, as Dr. BURNS said, "to surrender to the commonplace mind."

Decline in Vaccination

THE Vaccination Acts of 1867–1907, for many years more honoured in the breach than the observance, were repealed by the National Health Service Act; so since July 5, 1948, all semblance of compulsion has been removed. The popularity of diphtheria immunisation, when offered to young children on a voluntary basis during the war, led those responsible for part III of the Act to hope that the removal of compulsion, backed by a tactful approach to parents, would stimulate rather than discourage infant vaccination. The late Professor GREENWOOD,[4] on the other hand, forecast a decline in vaccination to a negligible figure unless there was an epidemic of major smallpox sufficiently severe to alarm the public, as happened in 1901–02. CONYBEARE's summary[5] of the figures in England and Wales for the first six months of the service shows that, though there are wide local variations, this forecast has in general proved correct. In England only just over 18% of the children born in the first half of were vaccinated *before* the end of the year and Wales barely 10%. The comparable figure for Englan and Wales during the ten years 1937–46 was 36·8% so the proportion of children vaccinated duri the first year of life has been halved.

It is now nearly 50 years since the severe form smallpox was sufficiently widespread in this count to make parents anxious to have their childre protected. The comparatively mild form which w intermittently prevalent from 1923 until 1932 cause relatively few deaths, and this fact, together wi the prompt localisation and suppression of outbreal arising from the importation of cases of major smallp from abroad—for instance, in connexion with t S.S. *Mooltan*—seems to have given parents an i founded and dangerous sense of security. Th the proportion of infants vaccinated did not fall ev below 37% was largely because the "vaccinatio paper," which every parent received when his chil birth was notified, served as a reminder, and becau the public-vaccinator system made it almost easi to have the child vaccinated than to refuse. At t inception of the N.H.S. the parents of about 50 of the children born declared a conscientious objecti to vaccination; 10% did nothing about their leg obligation under the Vaccination Acts, and wh followed up either could not be traced or persist in doing nothing unless they were prosecuted, whi was in practice futile; about 10% deliberate sought vaccination; and the remaining 30% accept it when it was offered conveniently either by t public vaccinator in the home or at a clinic associat with a local-authority welfare centre.

It is highly improbable that about July, 194 many parents suddenly decided that vaccination w undesirable, though the abolition of compulsi certainly acted as propaganda for the antivaccin tionists. Thus in Manchester, a sample survey November and December, 1948, showed that out 2259 parents of infants aged 4–6 months, 13 desired vaccination.[6] The most important cause the recent decline is undoubtedly the disappearan of the office of public vaccinator. The general prac tioner who formerly filled this post has for t present too much other work resulting from the n Act to spare time for special visits to those infan in the families on his list who have reached a suitab age and for persuading their parents to have the vaccinated. Parents, though perhaps approach by the health visitor and favourably disposed vaccination, are understandably disinclined to sw their doctor's surgery queue, and even if they thi of asking the doctor to visit them for this purpo not all doctors will agree. There remains the loc health-authority clinic, which does not always exis There may not be many doctors who, like our corr spondent Dr. MILLARD, are actively opposed infant vaccination; but a large proportion a apathetic. And their apathy is being sustained b the unfortunate disagreement between the negotiati committee and the Ministry on the fee for notifyi successful vaccinations. The Ministry's view, th an accurate record of vaccination (or immunisatio deserves no higher fee than the notification

tious disease. is unlikely to be acceptable: and awhile the M.O.H. who embarks on a vaccination paign is often deprived of his strongest ally— family doctor. Moreover, while the fee remains ecided there is a greater likelihood of vaccinations by practitioners not being recorded, and therefore included in the published figures. Inquiry in chester shows that since the Appointed Day about of the vaccinations done have not been notified; e represent 3·8% of the infants born.

ow can the position be improved? In some places, Leicester, which has an antivaccinationist tradi- almost as old as vaccination itself. and which s CONYBEARE's table with 1·4%, this may be a h proposition. though if smallpox did arise in neighbourhood there would probably be no culty in persuading contacts to be vaccinated. e usually it is inaction rather than opposition the part of parents which has to be overcome, first step is to reinstall a system of reminders. Canterbury when a birth is notified the parents eive a postcard telling them how to arrange for vaccination from their doctor or the clinic; necessary they get a second postcard when their y is 3 months old; and when they bring their ld for diphtheria immunisation they are again ted about vaccination. Some such practice should general. The other essential step is to remove the rental inconveniences of vaccination. In rural as a return to some domiciliary system seems avoidable, and even in towns the personal persua- n of a public vaccinator, calling at the child's me, would be a valuable support to the M.O.H.'s opaganda. If the parents of all children who had ached their fifth month without responding to e M.O.H.'s reminding notices were visited by public vaccinator large numbers of the present tagglers would certainly be rounded up.

Work the Old Can Do

LENGTHENING lives have dislocated the seven ages man. There are, of course, some lean and slippered ntaloons about, and every doctor sees cases of cond childishness and mere oblivion: but these anifestations of great age come on much later than ey used to do. The hale old man in the seventies d the hearty old woman in the eighties are beginning lose the charm of rareness: and nowadays rela- ely few people are really old at sixty-five. They ay have some signs of decline, such as failing sight or earing, and loss of muscular power; but. as Sir RNEST ROCK CARLING pointed out at a conference[1] n Oct. 14, these defects are not the prerogative of d age. The old are often said to have less endurance han the young; and will themselves assert with ride that you can't teach an old dog new tricks. But all depends (as we have learned to say) on what you ean by endurance, and what kind of tricks you propose to teach. In industry during the war absence-rates are said to have been no higher among the old than among the young; and work at Cambridge has shown that the elderly can master new techniques. They learn more slowly than the young, certainly, but they also learn more carefully: they destroy less material in the process and they take much better care of tools.

This is not to deny that there are many old. ailing, and neglected people in the country: in the last few years we have become increasingly aware of them; and indeed their needs have been considered more and more seriously ever since the first old-age pensions were granted in 1908. But it is also true that for men of sixty-five the expectation of life is nowadays 11·68 years. while for women at sixty it is 17·13. The retiring age of sixty for women and sixty-five for men was presumably fixed on the understanding that most people would observe the Psalmist's threescore and ten. It seems, at first glance, to be both grudging and fluffy-minded to give adequate retirement pensions and then point out that there is plenty of good work left in the retired; but that is what comes of trying to lump people together and judge their capacity by their age. Speaking at the same conference, Mr. W. A. SANDERSON, assistant secretary of the Nuffield Foundation, outlined the position in which this failure to discriminate will ultimately place us. To care for 50,000 sick old people in hospitals, and to house and look after a further 55,000 in residential homes and institutions already costs us £20–25 million a year. These represent only 1 in 60 of people of pensionable age in the country, and many could do with such care who are not getting it. The Royal Commission on Population[2] stated that in 1947 the pension scheme was costing £265 million, more than half of which came from the taxpayer. The number of people of pensionable age (already 6 million) is to be 8 million by the end of the century: and if all of these claimed pensions they would cost 4*s*. in the £1 in income-tax. This. said Mr. SANDERSON, is not an argument for going back. or going slow, or reducing pensions; but it *is* an argument for not putting anything in the way of those who want to go on working. We can only give pensions up to the limit of our capacity—that is, up to the limit of what we produce. If we want more for old people we must work more and they must help us. The size of the future labour force will not increase and may decline. The extra year of schooling will lose us a third of a million workers, and the county colleges will lop man-hours still further.

Many men dislike retiring at sixty-five; and some even seem to decline to death from the effects of idleness and boredom. Mrs. LEWIS told of men who after retirement catch the same train in the mornings as they have always done, spend the day in the public library, and catch their usual evening train back, merely for the sake of exchanging gossip with their friends. For many people, to retire is to lose a great part of their social life. The self-employed man rarely gives up work at sixty-five; and women never retire at all from housework. Again. retirement is not exacted in all callings; ancient judges are a commonplace on the bench, old actors fall into new parts, old professors contribute their knowledge and experience to university life. Nor do all firms insist on a compulsory retirement age: though banks and public services nearly always have rigidly enforced rules, in reaffirming our own faith in it we must admit that the only convincing test is experience. Since in fact a considerable number of consultants are assisting the Distinction Awards Committee against what they believe to be their better judgment, and others have refused to assist at all, might it not be best to meet the objectors and the doubters by declaring that the scheme is experimental—by setting a term of perhaps five years to the awards now made, after which consultants as a body could themselves decide whether it be discontinued or altered? If this novel system of remuneration were introduced in the form of a terminable trial rather than as an irremovable feature of the new service, it might be more acceptable to the minority who are not yet convinced that it is sound.

[2] Report of the Royal Commission on Population. H.M. Stationery Office, 1949. See *Lancet*, 1949, i, 1105, 1110.

On the other hand we have no doubt that the system, experimental or not, should now be introduced, and we believe the majority of consultants to be of the same opinion. The mechanism by which, under the old order, special merit was specially rewarded has largely broken down in the National Health Service, and it needs to be redesigned in one way or another. We share the view of Dr. BURNS[3] that the kind of distinction that ought to be recognised is "distinction in professional service to the community," and we hold that the profession is on the whole capable of assessing such service more justly than the laity. Of course, general practitioners and patients will be foolish if they suppose—as some of them will—that a consultant is necessarily less suitable for their purpose because he has no award or because it is not the highest: every wise man should know that rank of any kind is but the guinea stamp. But what Dr. WALSHE derisively terms "a first, a second, or a third class 'distinction' label issued from Whitehall" should at worst be no more misleading than the title, the car, the clothes, and the address, by which the standing of the specialist has too often been judged in the past. And to accept at this stage the alternative of standard salaries would be, as Dr. BURNS said, "to surrender to the commonplace mind."

Decline in Vaccination

THE Vaccination Acts of 1867–1907, for many years more honoured in the breach than the observance, were repealed by the National Health Service Act; so since July 5, 1948, all semblance of compulsion has been removed. The popularity of diphtheria immunisation, when offered to young children on a voluntary basis during the war, led those responsible for part III of the Act to hope that the removal of compulsion, backed by a tactful approach to parents, would stimulate rather than discourage infant vaccination. The late Professor GREENWOOD,[4] on the other hand, forecast a decline in vaccination to a negligible figure unless there was an epidemic of major smallpox sufficiently severe to alarm the public, as happened in 1901–02. CONYBEARE's summary[5] of the figures in England and Wales for the first six months of the service shows that, though there are wide local variations, this forecast has in general proved correct. In England only just over 18% of the children born in the first half of 1 were vaccinated before the end of the year and Wales barely 10%. The comparable figure for Engl and Wales during the ten years 1937–46 was 36·8 so the proportion of children vaccinated duri the first year of life has been halved.

It is now nearly 50 years since the severe smallpox was sufficiently widespread in this to make parents anxious to have their ch protected. The comparatively mild form which intermittently prevalent from 1923 until 1932 caus relatively few deaths, and this fact, together wi the prompt localisation and suppression of outbrea arising from the importation of cases of major smallp from abroad—for instance, in connexion with t S.S. *Mooltan*—seems to have given parents an founded and dangerous sense of security. Th the proportion of infants vaccinated did not fall ev below 37% was largely because the "vaccinati paper," which every parent received when his chil birth was notified, served as a reminder, and becau the public-vaccinator system made it almost eas to have the child vaccinated than to refuse. At t inception of the N.H.S. the parents of about 5 of the children born declared a conscientious objecti to vaccination; 10% did nothing about their le obligation under the Vaccination Acts, and wh followed up either could not be traced or persist in doing nothing unless they were prosecuted, wh was in practice futile; about 10% deliberat sought vaccination; and the remaining 30% accep it when it was offered conveniently either by t public vaccinator in the home or at a clinic associat with a local-authority welfare centre.

It is highly improbable that about July, 19 many parents suddenly decided that vaccination w undesirable, though the abolition of compuls certainly acted as propaganda for the antivacci tionists. Thus in Manchester, a sample survey November and December, 1948, showed that out 2259 parents of infants aged 4–6 months, 1 desired vaccination.[6] The most important cause the recent decline is undoubtedly the disappeara of the office of public vaccinator. The general prac tioner who formerly filled this post has for t present too much other work resulting from the n Act to spare time for special visits to those infa in the families on his list who have reached a suita age and for persuading their parents to have th vaccinated. urely what the patient wants is what most of us it in our own homes—something that will enable o look tidy without actually being tidy. A sizeable board, in short, with an easy door which will t away our iniquities. The nurse wants it too; can empty it quickly, clean it easily, and tidy it in a minutes. This bedside cupboard should be raised l from the floor, so that the patient need not stand his head to get anything out of it, and should e a few shelves in it so that clothes and books be separated from food and soap-dish. Though B.S.I. include a cupboard (or even cupboards) in st of their designs, its potential capacity has nearly ays been reduced in favour of pigeon-holes. In the design illustrated here there are no less than five pigeon-holes (one being round at the back). The etceteras are drawn from our memory of a similar locker in use. Sliding tables, such as that shown here, are, we believe, best avoided in the interests of cleanliness and simplicity.

The B.S.I. do not favour drawers, which they say are difficult to clean; but the designer's wife could tell him how much easier it is to take out a drawer and turn it upside down than to pry into the recesses of a cavity. Besides a roomy cupboard, the patient ants a shallow loosely running drawer near the top the cabinet, in which he can keep his money and s pipe (or her knitting and her powder). As gards the two towel-rails, there are many moments a leisurely fruit-eating day when one wishes to ipe the fingers on a hand towel, but bath towels ould be hung where they can dry completely; and the ward has no airing cupboard with numbered ils, then the hospital carpenter should be asked to it a plain bar over, or to one side of, the radiators etween the beds. Towels folded neatly and hung these would not look as unsightly as the clumsy indle now crammed on locker-backs—indeed, loured towels could look very pleasant.

For social life as lived in the ward the patient ill ask no more of his locker than a cupboard, a rawer, and a single rail. He will find, however, at some other obligations are thrust upon him. hat is he to do with a full urine bottle until the urse comes to collect it? The B.S.I. are rightly against is using the recesses of his locker as a resting-place for ; but there they dismiss the distasteful subject, leaving he patient holding his bottle. This can be a lengthy nd even tiring occupation in an understaffed ward. hat he needs is some kind of rack, on a level with he bed, which will hold the vessel at a safe angle and rotect it from sudden jolts. In men's wards a chromium r wooden shelf set at an appropriate angle, and with raised edge, might well be attached to the side of the locker at such a height that the patient could slip the bottle on to it with little effort. This would also encourage the quick removal of bottles, for though a busy nurse may forget to collect a concealed bottle, she would naturally take in passing any that she could see at a glance.

The B.S.I. offer many sound reflections on material. Wooden lockers stand up to hard wear, but only if they are well made and waterproof at the joints. Metal lockers are apt to be noisy unless special sound-deadening measures are taken. Plastics used as finish should be chosen with discretion, since some resist heat well, but others are easily spoiled by it. These and many other facts set out in their draft deserve study by all interested in this fascinating and universal piece of hospital equipment. The B.S.I. invite criticism and comments, and these should reach the institution before Oct. 29.

THE M.O.H.

The difficulties of public health, which Dr. Brockington describes on another page, were emphasised by Dr. H. C. Maurice Williams in his presidential address last Thursday to the Society of Medical Officers of Health.[1] He spoke of profound despondency among members of the public-health service about its future, of failing recruitment, and of disintegration. But he warned his hearers of the danger of a dismal outlook which may end by making people believe that the M.O.H. has outlived his usefulness. What the situation really demands is a renaissance.

Dr. Maurice Williams hoped, without much apparent conviction, that in the future, under the new régime, the people are going to get a better medical service than they got through the panel, the hospital contributory schemes, and the local authorities. Meanwhile he clearly feels that in some respects the practice of public health has become harder since July 5, 1948. It was, he said, an administrative blunder to place the infectious-diseases hospitals under the regional boards, removing them from the sphere of the M.O.H. who is still responsible for the ascertainment and control of epidemic infections. "There is a grave threat that the medical officer of health may be displaced in his field work by the general physician and pædiatrician"; which would be wrong because "the epidemiological unit is a number of individuals making up a population, and needs more than the clinical diagnosis or treatment of the individual case." Similarly the tuberculosis service has been mainly divorced from preventive medicine: "the change of designation of the responsible officer to that of chest physician will in itself encourage a tendency to concentrate on the more spectacular curative side of the work." To secure early treatment of the teeth of the priority classes, Dr. Maurice Williams thought that dentists in the N.H.S. would have to be asked to undertake one or two sessions each week in the local authorities' dental clinics.

> "The disastrous collapse of the school dental service should be a warning to those responsible for the future of the health scheme to think again before suggesting any alterations which will bring what is left of the school health and welfare services into the same state of chaos. The family unit idea of medical care by the general practitioner is, in theory, a reasonable conception; but in practice the ascertainment and follow-up of defects in children, many of whom belong to apathetic parents, requires an organisation capable of a systematic check on the periodical medical inspection and the correction of the defects found."

---

[1] The address will appear in full in the November issue of *Public Health*.

there are many industries, including road transport, in which retirement is rarely required at a fixed age. Manual workers, however, often find that though no rule obliges them to retire, the conditions of their work may become too heavy for them in the later sixties. Some firms, taking this into account, find appropriate work for their own old employees who want to go on working; but very few will take on an old man who has been with some other firm. If the industry is a heavy one there may be no place in it for the elderly, and a man may thus be obliged to retire simply because he cannot find work suited to his capacity. It is no good "preferring" to go on working, Mrs. LEWIS said, if there is no work to be had.

Sir ERNEST ROCK CARLING suggested that if those past retiring age are to continue at work the sympathy of the employers, the trade unions, and the shop stewards must be engaged; and there was evidence from other speakers that this is not so formidable a task as might be supposed. Fellow workers, it seems, are nearly always sympathetic, and will work with an elderly man without resentment, arranging among themselves to spare him the heavier tasks. A shop steward reported that on a recent occasion when redundant staff was being dismissed, two younger men volunteered to go in place of two old men who stood next on the list for dismissal. Skilled old men encounter no problem: some up to eighty or eighty-five are to be found at work in industry, most of them ready to extol the virtues of age and experience. Nevertheless, if a large number of those past retiring age are to be encouraged to go on, some special conditions, Sir ERNEST said, are necessary: there must be no unemployment in the country, no question of using old people as cheap labour, and no detriment to their health; and they for their part must be willing to resign senior posts to juniors needing promotion. Some slackening off is permissible: they should get the same rate per hour but may be allowed to do fewer hours. It seems that in one industry at least this has been achieved; for in London many dockers between the ages of sixty-five and eighty are still at work. The elderly do not stand up well to hurry or to transport difficulties; and some firms arrange that they come ten minutes later and leave ten minutes earlier than the other workers, so that they miss the rush-hours on the buses. In other firms they are given work usually done by women or young people; but old men are apt to resent doing work usually done by women, though they will consent to do boys' work. Sometimes a whole department can be turned over to them. In one firm the filing and internal messenger systems have been reorganised so that old people can manage them instead of juveniles. It costs a little more, but the work is done more efficiently. The old people had to learn the job, and they take their time about it; but they are more reliable than the youngsters, and keep their minds on what they are doing. "There's no larking about on the stairs," as Mrs. LEWIS said.

As an *inducement* to continue in work, people are now offered an eventual addition of 1s. a week to their pension for every six months' employment beyond the age at which they are entitled to retire: *the Chief Press* Officer of the Ministry of Pensions, explaining this arrangement in more detail,[3] tioned that at present about two-thirds of the men reaching minimum pensionable age, and *half of the insured women, do not* claim th retirement pensions, because they are continuing regular work until later. The feeling at the conferen however, was that this inducement is too small encourage people to postpone retirement, though very well for those who want, and are in a go on working. Whatever the method, the p of making continued work seem inviting is sound. Economic necessity is one reason for doi this, but there is a better one. Thanks to one thi and another, we live longer than our forerunne and if geriatrics prospers our older people should not only alive but lively. Without prejudice to th who become infirm—and who must of course be giv more and better care of the kind we have lately be trying to offer them—the healthy old must have th chance to be active and useful. The lonely unoccupi old person is always bitter at his uselessness. Th sensible suggestion, made at the conference, that th public services should abolish their compulsory retire ment rules, would save many years of work which wil otherwise be lost, and give a lead to the whole country but it would do much more than that.

Bedside Lockers

BY those who design bedside lockers two opinions must be taken into account: that of the patient who always feels that there is no room for half th things he needs; and that of the nurse, who alway thinks that patients collect a lot of rubbish. Thes have been borne in mind by the British Standards Institution (B.S.I.), who have published some draf designs.[4] An efficient locker, they say, can lighter the work of the nurses and domestic staff and heighten the comfort of the patient; but it must be admitted that in these respects the designs they submit, despite several good points, are somewhat disappointing. Eight models are proposed, five of them general-purpose lockers, one for infectious-diseases hospitals and two for children's wards. They are all tall lockers, with their tops at a convenient level for the patient to reach from his bed, and all appear neat and plain—and empty—in the pictures. Nearly all of them have one or several open compartments—for books, papers toilet articles, and such personal effects as pipes and cosmetics; and most of them carry two rails—for bath and hand towels. Some have a third rail to carry a canvas bag for dirty handkerchiefs. But have the designers ever seen lockers of this type in action in any "long-stay" ward? They will find that the compartments are all filled to overflowing; papers stick out untidily; the top becomes crowded with sewing, painting, buns in paper bags, and bottles of sweets; books get stuffed into shelves at awkward angles; towels form a damp bunchy bustle round the back, and the whole effect is one of rakishness without charm. The little pigeon-holes which seemed so exactly fitted for their purpose by the designer are always subverted to other purposes by the unquenchable variety of patients. *Moreover* such *cavities* are maddening to clean out, because their inmost corners, rts of crumbs and dust, are always in shadow. locker with pigeon-holes can possibly lighten the urs of nurses and domestic staff.

It was, he said, an administrative blunder to place the infectious-diseases hospitals under the regional boards, removing them from the sphere of the M.O.H. who is still responsible for the ascertainment and control of epidemic infections. "There is a grave threat that the medical officer of health may be displaced in his field work by the general physician and pædiatrician"; which would be wrong because "the epidemiological unit is a number of individuals making up a population, and needs more than the clinical diagnosis or treatment of the individual case." Similarly the tuberculosis service has been mainly divorced from preventive medicine: "the change of designation of the responsible officer to that of chest physician will in itself encourage a tendency to concentrate on the more spectacular curative side of the work." To secure early treatment of the teeth of the priority classes, Dr. Maurice Williams thought that dentists in the N.H.S. would have to be asked to undertake one or two sessions each week in the local authorities' dental clinics.

> "The disastrous collapse of the school dental service should be a warning to those responsible for the future of the health scheme to think again before suggesting any alterations which will bring what is left of the school health and welfare services into the same state of chaos. The family unit idea of medical care by the general practitioner is, in theory, a reasonable conception; but in practice the ascertainment and follow-up of defects in children, many of whom belong to apathetic parents, requires an organisation capable of a systematic check on the periodical medical inspection and the correction of the defects found."

---

[1] The address will appear in full in the November issue of *Public Health*.

In pressing for the early construction of health centres "while the doctors are still in the mood," he evidently had in mind the kind of centre in which clinics would be prominent.

Whatever the M.O.H. has lost, there is no denying that his experience and his imagination are badly needed in the work that remains, where he has been given important new powers. Here Dr. Maurice Williams spoke particularly of the development of domiciliary nursing services (making more use of part-time married nurses) and the home care of the aged and infirm. Part of the function of the M.O.H. will be to teach people to use the medical services widely and unselfishly, and he must try to bridge the gap now existing between the hospital, the local authority, and the general practitioner. Unfortunately, in the N.H.S., "the maintenance of health has not been given the same consideration as the cure of disease. Yet the present national expenditure can be justified only on the basis that the essential aim of the service is to prevent illness." Dr. Brockington enlarges on this last theme when he shows how the power over medical resources has been given to the regional boards. The M.O.H. wanting the help of a pædiatrician or an obstetrician to develop *preventive* services must appeal for such help to a body which has no responsibility for prevention and can scarcely be blamed if it prefers to reserve its specialists for its own curative work. In deciding how resources should be allocated there is nobody in a region whose duty it is to take a balanced view of the community's needs, and nobody who can argue on equal terms with a board which thinks that hospitals are what matter in medicine. Dr. Brockington's solution of this problem may or may not be the right one; but some solution must certainly be found.

ANTIBIOTICS AND COAGULATION

ACCORDING to the *Manchester Guardian* (Oct. 15, p. 5) Dr. Alton Ochsner says there has been a serious rise in the thrombo-embolic complications of surgery since penicillin and other antibiotics have been used as a routine. He told the New Orleans meeting of the International Society of Surgery that at Tulane, where he is professor of surgery, there were as many cases in the two years after the introduction of penicillin as there had been in the preceding five years.

The possible danger of penicillin causing thrombosis has, of course, been pointed out before. In the early days of penicillin, when it was given by continuous intravenous-drip infusion, one of the most troublesome reactions was venous thrombosis. Intravascular clotting and in-vitro clotting of shed blood are not directly comparable, but investigations were made to see whether penicillin shortened the coagulation-time. Moldavsky and his co-workers[1] and Macht[2] found that it did (Moldavsky reported that the bleeding-time, which depends on a different mechanism, was also affected), but Lewis[3] and Ungar[4] could not confirm their findings. Estimations of coagulation-time are notoriously open to error and need repeated confirmation. These observations were inconclusive because not all the factors entering into the clotting mechanism were evaluated, and neither the methods of administration nor the doses of penicillin were standardised. Fleming and Fish,[5] on the other hand, came to the conclusion that locally applied sodium penicillin, in oral surgery, delays coagulation. More recently Weiner and others[6] administered large doses of penicillin intramuscularly and estimated the prothrombin-time of whole and diluted plasma, the coagulation-time, platelet-count, pla adhesiveness, and plasma [illegible] when the blood-penicillin [illegible] again when penicillin had disappeared from the blood the two sets of values did not differ significantly. Th was reassuring, but in the light of Ochsner's experien further work on the subject seems called for.

Reports on the effect of streptomycin on [illegible] coagulation have also been conflicting. Macht [illegible] in animals that streptomycin given parenterally [illegible] the coagulation-time. But, Farrington and his co workers[8] reported that in human subjects coagu time and prothrombin-time remained within limits; and this was confirmed by Elson[9] in a study tuberculous patients. The effect on blood-coag of the newer antibiotic, aureomycin, has been by Macht and Farkas.[10] In both man and anim prothrombin-time was unaltered, but in some subjec the clotting-time was appreciably reduced. This al needs watching, though hitherto patients receivin aureomycin have shown no signs of an increased liabilit to thrombo-embolic accidents. In theory the adminis tration of antibiotics by mouth might interfere wi blood-coagulation because they inhibit the growth intestinal organisms that synthesise vitamin K, and th vitamin is essential for the formation of prothromb and therefore for the coagulation of blood.

MYELOSCLEROSIS

MYELOSCLEROSIS is one of those rare conditions th entrap the unwary surgeon who removes large splee without submitting the patient to a thorough hæmato logical investigation. Briefly, what happens in th disease is that the bone-marrow undergoes a curiou fibrosis that slowly strangles the blood-forming element at the same time the spleen enlarges and blood formatio begins again in its embryonic site. But this blood forma tion in the spleen cannot keep pace with the needs of th adult body, so the patient develops a slowly worsenin anæmia; primitive white cells, even some myeloblast nucleated red cells, and sometimes megakaryocyte appear in the peripheral blood. The spleen become enormous, but if it is removed the sole remaining sit of blood formation goes, and the patient soon die Left alone, the patient may carry on, with diminishin efficiency and increasing discomfort, for some year The diagnosis depends on the blood picture, the failur to obtain any cellular bone-marrow by needling, an the radiological changes in the bones. The bloo picture is not characteristic, since the same pictur can occur in some forms of myeloid leukæmia, and some what similar changes can appear in all the variou diseases that cause leuco-erythroblastic anæmias. Punc ture of the sternum and iliac crest does not yield an cellular marrow; the final proof should be a trephin sample of sternal marrow and confirmation of the typic histological changes. Radiography sooner or later show narrowing, or even obliteration, of the marrow cavit in the long bones, especially in the femurs.

Unfortunately the findings are not always so clear-cu and in this issue Wood and Andrews describe 3 case that were much less typical. Differential diagnosi has given rise to much difficulty in the past, particularl between myelosclerosis and subleukæmic or aleukæmi forms of chronic myeloid leukæmia. In smears o normal bone-marrow, myeloblasts, monocytes, an lymphocytes are present only in small numbers; s whatever the picture in the peripheral blood, when th bone-marrow shows large numbers of these cells a diagnosi of leukæmia is almost certain. But in chronic myeloi leukæmia the cells involved are myelocytes, metamyelo [illegible] and the bone-marrow can sho

ority of these cells in many other conditions besides mia. The diagnosis of subleukæmic or aleukæmic ic myeloid leukæmia thus depends on the failure d any other cause for the enlarged spleen. the ely few (if any) immature cells in the peripheral and the demonstration of a cellular bone-marrow ps containing more early granulocytes—promyelo- and myelocytes—than usual. The presence of basophil granulocytes in the marrow is suggestive ıkæmia, and there is often a striking increase gakaryocytes in the marrow and spleen. This ion, or one very like it, is described in America the name "agnogenic myeloid metaplasia" [1] se of the granulocytic and megakaryocytic hyper- in sites other than the bone-marrow, again ularly in the spleen.

differential diagnosis between leukæmia and sclerosis may thus depend entirely on the bone- w findings—in leukæmia a cellular marrow with al numbers of granulocytes and megakaryocytes: elosclerosis a marrow almost devoid of cells argely replaced by fibrous tissue. Before bone- w biopsy became a standard technique the two ions were confused and consequently most of the its before about 1940 are not very helpful. With t knowledge the differential diagnosis can be made t cases, and this is not merely an academic exercise, e the newer sclerosing forms of treatment. like en mustards, may be useful in leukæmia but are ely dangerous in myelosclerosis.

A NEW CODEX

E are the days of the iconoclast who boasted that ld conduct his practice on a quarter of morphine catheter. The 20th century is a notable epoch of eutic development, and there never was a time offered greater opportunities or greater privileges hose now enjoyed by the practitioner of medicine. benefits, however, cannot be dissociated from sibilities. The essential preliminary to effective ent is accurate and comprehensive diagnosis; e pre-requisite of skilful prescribing is an intimate edge of the scope of well-established drugs. It t be said too often or too emphatically that well- ed physicians and surgeons seldom require to look d official and semi-official publications for thera- and diagnostic agents. It is incumbent on the l teachers to support their colleagues in the depart- of pharmacology and therapeutics by insisting on e of the official names for drugs, and on prescriptions test the student's knowledge of the principles of acology and the elements of pharmacy.

ention has been repeatedly drawn to the growing tance of the *National Formulary* as a practical to prescribing; but it does not offer the back- d information that all of us sometimes seek. medical practitioners find that the *British Pharma- a* meets their requirements; it is essentially a book erence for the pharmaceutical chemist and drug facturer. On the other hand, all can find much is of interest and of practical value in the *British naceutical Codex*, because facts about drugs and preparation are supplemented by concise state- s of therapeutic actions. The structure of the new n [2] is similar to that of its four predecessors, though e age of 42 years there is more than a hint of middle- pread. Nearly two-thirds of the 1500-odd pages levoted to general monographs which embrace all reparations and substances included in the *B.P.*; ot infrequently less space is devoted to preparation to action and uses, and there are lively descriptions ugs which are not official, such as tea, coffee, yeast, Irish moss, and lily-of-the-valley flowers. Let no highbrow pharmacologist in his laboratory despise these comforting and time-honoured remedies. Part 2 is concerned with antitoxic, antibacterial, and antiviral sera. This section is as readable and informative as any textbook on the subject; and the decision to separate it from the general monographs was wise. The wide appeal which the *Codex* undoubtedly makes is maintained by such lucid reviews which are not excessively technical. The same observation might be made on part 3, which discusses preparations of human blood. Any suspicion of atavism is dispelled by the inclusion among these invaluable substances of human fibrinogen and human thrombin. How many surgeons can explain the differences between a crêpe and a domette bandage? The information is readily available in the section on surgical ligatures and sutures. The pièce-de-résistance, however, is clearly the formulary. extending to upwards of 300 pages. Here elegant prescriptions abound. and every form of medicament is generously represented—creams. dusting-powders, elixirs, emulsions, capsules, linctuses, and injections, to mention only a few taken at random. It is true that their features are not extolled on blotting-paper, but their reliability and purity are guaranteed by the panel of distinguished pharmacists and physicians who have fought assiduously to attain the highest possible standard. Issued with the volume is a folder giving in alphabetical order the *Codex* names of preparations and their proprietary equivalents.

The Pharmaceutical Society, which has rendered such a signal service to the medical profession as well as to its own members by publishing the new edition of the *Codex*, would earn the gratitude of practising doctors by sending them a copy of this useful supplement.

HEMP

CANNABISM is the easiest choice for the addict. The varieties of *Cannabis sativa* grow readily in various climates: where the atmosphere is cold or temperate, the subsoil moist, and rain abundant, the plant grows soft fibres which can be sold for rope-making; but in a hot climate with a dry soil the plants are small and tough, and secrete more abundantly the resin which is marihuana—or bhang, hashish, kif, dagga, anascha, esrar, diamba, or maconha. The drug is commonly taken in cigarettes, usually made from the flowering tops, rich in resin, of the female plant; and, though it is cheap enough, the habit of adulterating drugs is so powerful among illicit traders that they cannot always resist putting in a mixture of other weeds, fortunately harmless.

Dr. Pablo Wolff, whose lecture delivered last year to the Sociedad de Medicina Legal y Toxicologia of Buenos Aires has now been translated,[1] attributes the spread of the drug in the Latin Americas largely to the ease with which it can be grown and distributed. A spreading centre of traffic in this drug is situated in the north and north-east of Brazil, where the cannabis plant grows wild. Users are among the poorer groups—natives, farm hands, packers, fishermen, sailors, and vagrants. Soldiers may also become addicts, and so may women, though in far smaller numbers than men. In Brazil, Mexico, and Cuba, marihuana parties may be held, sometimes as religious rites of secret societies, in which a convivial exhilaration among the guests at the start is apt to give place to hallucinatory excitement, uproar, strife, and exhausted sleep. This picture fits in with the findings of those scientists who have investigated the effects of marihuana either by clinical observation or personal trial. This drug reveals the subconscious tendencies of those affected, often in practical action of an aggressive or otherwise undesirable kind: and the

affected person may feel driven to do the thing he knows to be wrong, or at least powerless to prevent himself from doing it. When he recovers he may have forgotten the entire episode; Dr. Wolff records a particularly unhappy case of a youth of nineteen, pleasant and of good character, who under the influence of the drug killed five of his family, and afterwards only remembered a terrible dream. Other cases are recorded of soldiers or policemen shooting people without warning or provocation. The drug, he believes, also predisposes to sexual offences; and it may be taken deliberately by criminals to nerve themselves for a murder, assault, or other crime: indeed, the word "assassin" derives from "hashish." It is only fair to recall, however, that some other authorities—notably Bromberg [2]—are sceptical of these grave effects. Bromberg asserts that in 67 criminals with marihuana addiction he found no positive evidence of a relation between this drug and sexual or violent crimes; but Wolff holds that the grounds on which he made this judgment were inadequate. Dr. J. D. Fraser's paper in our present issue shows that irritability culminating in violence may develop when the addict is deprived of his drug.

Wolff reports that the secret cultivation of hemp flourishes in Mexico, which boasts a plant particularly rich in resin. Hemp was introduced into Cuba 30 years ago by Portuguese sailors; and by 1946 70–80% of the drug-addicts there were users of marihuana. Cuban attempts to suppress the trade are at present feeble. In Colombia, however, stricter legislation is being passed as a result of an alarming spread of addiction in the cities. The use of the drug is so far limited in Ecuador, but is spreading in Central America, and is established in the countries of the Carribean. Argentina is for the most part free of this form of addiction, only a few cases having been reported; the Argentina police, moreover, have been active in suppressing every attempt to introduce hemp. Wolff mentions the spread, during the past 15 years, of marihuana addiction in the United States. His concern at the general picture must be generally shared, for this drug destroys the addict's relation to society and makes him a member of a special class of vicious and delinquent characters. There are more ways of killing a man with hemp than by hanging him.

PITUITARY, ADRENALS, AND RHEUMATOID ARTHRITIS

On July 23 we discussed Hench's fundamental work on the action of 'Cortisone' and anterior-pituitary adrenocorticotropic hormone (A.C.T.H.) on rheumatoid arthritis and rheumatic fever. A paper in the *Practitioner* by Thorn and Bayles,[3] of Harvard, carries the work of the Mayo Clinic investigators a stage further.

It had previously been shown by Thorn, Prunty, and Hills [4] that four hours after a dose of 25 mg. of A.C.T.H. the number of circulating eosinophils is much reduced in a normal person but not in a patient with Addison's disease. This provides a sensitive test of the efficiency of adrenal cortical function; but it is possible to go physiologically a stage further back: if 0·3 mg. adrenaline is given subcutaneously, there is also a fall in eosinophils, the mechanism of this being

$$\begin{tikzcd} \text{adrenaline} \arrow[d] & & \\ \text{hypothalamus} \arrow[r] & \text{anterior pituitary} \arrow[r, "\text{A.C.T.H.}"] & \text{adrenal cortex} \end{tikzcd}$$

So while a positive A.C.T.H. test merely means an intact adrenal mechanism, a positive adrenaline response means that the whole hypothalamic-pituitary-adrenal system is working adequately. These tests have now been performed on a number of patients with rheumatoid arthritis, and nine out of ten gave a normal response to A.C.T.H. The response to adrenaline, though usually positive, was more variable, and some rheumatoid patients gav a positive A.C.T.H. response with a negative [illegible] effect: whether this is fortuitous, or due to a deficiency in the hypothalamic-pituitary link is not discussed

A.C.T.H. was then given for long periods to the t rheumatoid patients in amounts of 40 mg. per day divided doses: in nine cases the same dramatic improv ment as was described by Hench et al.[5] was observ while, as might perhaps be expected, the tenth patient, w had given a negative response to the test dose of A.C.T. did not respond at all to the treatment. In view of t shortage of A.C.T.H. and cortisone, attempts were ma to increase pituitary-adrenal stimulation less direct Adrenaline was tried in doses of 0·3 mg. six-hourly f fourteen days in two cases of rheumatoid [illegible] a slight, but definite improvement was observed, b much less than that obtained with A.C.T.H. or cortiso Evidence of cortical stimulation by the adrenaline w provided by the sustained fall in eosinophils and inc in urinary ketosteroids, but apparently this increase w insufficient quantitatively to be of real therapeutic val In rheumatic fever A.C.T.H. gave results as good as the obtained by Hench with cortisone. Equal benefit w observed in one case of disseminated lupus erythem tosus, and in gout: it is known that A.C.T.H. increa the output of uric acid, but the effects on the arthr were much greater than would be expected from t increased urate excretion, suggesting that here t there is a specific action on the joint tissues.

As regards the mechanism by which cortisone wor —either when it is administered as itself, or when it produced in response to A.C.T.H.—Thorn and Bayl do not express a definite opinion. As we have alrea remarked, it seems improbable that cortisone thera is merely replacement therapy. Thorn and Bayl point out that while 10–20 mg. of cortisone daily suffi for maintenance of a patient with complete adre insufficiency, 100 mg. a day is required to prod significant changes in the course of rheumatic dise and they state that "effective therapy is only attain when the level of hormone is clearly increased, eith from subnormal to above normal, or from normal above normal." The possible dangers of continu treatment with A.C.T.H. and cortisone are discussed A.C.T.H. has effects resembling those of desoxycort costerone [6] and long-continued A.C.T.H. therapy ma lead to persistent adrenal hyperplasia with the sympton of Cushing's syndrome. With the 40 mg. a day used b Thorn and Bayles, however, there has always be a rapid return to normal, or subnormal, levels of adre activity—the latter effect being perhaps due to suppre sion of the normal anterior-pituitary action by th exogenous A.C.T.H. In contrast, administration of cort sone may lead to atrophy of both pituitary and adrena and withdrawal symptoms may be severe: it is suggeste that this effect could be minimised by the use of A.C.T. for 24–28 hours after cessation of therapy with cortison

Unfortunately, the supply of A.C.T.H., which depe on the amount of pituitary glands available, is as limit as that of cortisone; and unlike the latter, which ma eventually be produced in adequate quantities b synthetic methods, it is likely to be always scarce. As w pointed out in the discussion reported on p. 749, th importance of Hench's work lies in the opening of a ne line of approach to the problems of rheumatism, eve more than in the discovery of a powerful therapeutic agen

Public Health

HE DIFFICULTIES OF PUBLIC HEALTH

PAST, PRESENT, AND FUTURE

C. FRASER BROCKINGTON
M.A., M.D. Camb., D.P.H.
ICAL OFFICER OF HEALTH, WEST RIDING OF YORKSHIRE

UBLIC health is an abstract idea; it has not the nour or drama of disease. The newspapers can a column with an account of the saving of life by eminent surgeon or physician called as a last hope by raught parents to the bedside of their child, or h a description of some novel operation on the heart brain. In contrast there is little news value in the ivities of public health; what is there to say about epidemic of typhoid fever that never occurred? blic health is a commercial proposition, yet it is only ely possible to demonstrate a cash return, or even to gest the existence of one: we cannot often point mpty fever hospitals, once filled with children suffering m diphtheria, whose annual costs of maintenance and ffing can be computed.

The idea that society as a corporate whole is just as ch in need of doctoring as any of its individual nponents has been slow to grow. Frank, in Bavaria, iting about 1780, recommended that a benevolent tator should take a wide range of action on the health nt; but though he wrote at great length during a g life, examining in minute detail the application of doctrine of "police medicine" to every aspect of , it is doubtful whether anyone in England read his rks. We in England preferred to attack the problems they arose or as we began to understand them, and to ve to other peoples the enforcement of entirely oretical ideas before they had been understood and epted. The Englishman's mind moves empirically; does not like to take, on theory alone, more than a all and hesitant step, and even this it prefers to leave some voluntary body. A long time has been needed prove in practice the economic, spiritual, and moral lues of schemes to safeguard the public health.

This piecemeal approach to the health of society s had a profound influence on the course of events in blic health. From the time in 1796 when Dr. Percival fired the minds of his fellow inhabitants of the city of anchester about the conditions in the cotton mills at they agreed to the establishment of a Voluntary ard of Health, right through the Industrial Revolution it darkened and worsened, action to achieve a healthy [illegible] was always taken on a narrow front. The [illegible] deal with an established evil have been given [illegible] ent to whatever body, central or local, seemed st fitted at the moment to wield them. There never as been a unified approach to the health of the community in any way comparable to our approach to the ealth of the individual. Whereas most people have ng agreed that it is best to have one doctor who can e you as an entire unit and can understand your roblems in relation to your whole life, the community as had to have its organs studied and treated separately.

Thus medical officers of health, first appointed in 847 to Liverpool, in 1848 to London, and in 1872 to the hole country, have never been given the whole field f work to tackle. As creatures of statute they have one what Parliament authorised them to do, and no more. Under the terms of the Sanitary Officers (Outside London) Regulations, 1935, the medical officer of health of a county has been given a function wide enough to capture the imagination of the most zealous ("he shall inform himself as far as practicable respecting all matters affecting or likely to affect the public health in the county"); but this does not enable him, or his authority, to play any real part in the services which are outside his statutory orbit. Some of public health, like the poor-law and factory health work, remained in the hands of central government departments for a hundred years; industrial medicine is still quite divorced from the rest of public health. Furthermore, owing to the growth of local government, public health as carried out by local authorities has been segmented; in counties—i.e., the whole of England outside the cities—it has been divided quite unnaturally between county districts and the county council, creating difficulties which schemes of "divisional administration" have helped to overcome.

The vast possibilities of public health were so little understood that Parliament failed at first to insist that medical men who took up such work must be whole-time. Contrary to the wishes of the Royal Commission on Local Government (1868), 70% of the medical officers of health appointed after 1872 were part-time in general practice, and of the 700 holding office today approximately 150 still remain so. Despite this faulty beginning, much of our success in England has resulted from the early development of a specialist qualification in public health. Soon after its creation in 1858 the General Medical Council was required to provide a special qualification in sanitary science, and in 1871 and 1875 Dublin and Cambridge offered diplomas—the first of all the specialist qualifications—for medical graduates seeking to take up such work. To hold such a diploma became obligatory for all except the small county districts after 1888. In this way the medical officer of health was trained "to become the voice of the community in which he was to be a leader and to urge at all times and in all possible ways that man should no longer be crippled by malnutrition, by slum dwellings, by lack of medical care, by social insecurity, and by disorders of personality." One of his most effective means of spreading these ideas has always been the duty imposed upon him, in 1870, to write an annual report of his work.

In recent years the development of public health has been affected by what may be called "the obsolescence of local government." When in 1939 Newman exulted in the greatness and success of local government, which after a century had gathered into its fold the poor-law administration and the duty of administering municipal hospitals, he failed to give due emphasis to the growing dissatisfaction with this form of government. The war seemed to bring this dissatisfaction to a head, and when peace came again it was evident that most people had lost confidence in the structure and saw little chance of executing the radical boundary alterations needed to establish units of administration capable of handling modern services. When the National Health Service was first suggested many said that the reorganisation of local government should be undertaken forthwith, so as to build the new service on new economic units. The Minister of Health said that this would be too long a process—a decision to some extent borne out by the subsequent inquiries of the Boundary Commission—and new machinery has been created, by-passing local government. Public health, being tied to local government, has had to suffer the nation's diminishing belief in local government.

To add to all these difficulties, and possibly transcending them, has been the continued opposition of the medical profession. In our teaching hospitals medical teaching has concentrated on the individual amidst all the paraphernalia of treating sickness; the student has gone from the bedside to the microscope or to the post-mortem room, but seldom out into the community itself. For a hundred years the medical officer of health has had to meet opposition and misunderstanding which has had its roots in teaching during the years of walking the wards, and he has himself been denied the new weapons and new disciplines which the universities and medical schools might have produced if their interest had been in the direction of public health. General practitioners have always resented the "interference" of local authorities in the free exercise of their work; the duty of making returns and notifications has been irksome and the services for school health and maternity and child welfare have seemed to come between them and their patients. The local authorities were almost the first contact which the general practitioner had with the "State" and he didn't like it.

DEVELOPMENT IN ISOLATION FROM CURATIVE MEDICINE

Sanitation and bad physical environment as causes of ill health were the first of the evil influences to be recognised and to become the basis of action by the State. The reason for this is to be found, not in any profound knowledge of medicine, but rather in our ignorance of it; for, since the days of the Greeks, putrifying stenches, or miasmas, have been regarded as the cause of plagues and pestilences. When in 1848 Simon was appointed to be the first medical officer of health of the City of London, bacteria had not yet been accepted as the cause of disease; yet he had little difficulty in convincing people of the iniquities of what he called "the pestilential heapings of human beings." If stenches were the cause of ill health, then there was reason enough in any London slum to assail the nostrils of anyone who cared to take a stroll among them: "what perambulations have I taken today in company with Dr. Southwood Smith," wrote Lord Shaftesbury in his diary for 1842; "what scenes of filth, discomfort and disease."

Thus public health began with its emphasis on environment in the sense of sanitation and infectious disease. These were the pressing problems of a hundred years ago. Duncan records that in the cholera epidemic in Liverpool in the early 1850s the dead were too numerous to bury. It is one of the very strange happenings of public health that the discovery of germs as the cause of infection did little to upset the fifty years' work which preceded that knowledge.

It was some time before public health began to widen the meaning of environment to include the personal habits of the individual and to add to its methods the detection of early disease. To understand that filthy slums can engender disease (even when the basis of the understanding is wrong) is not hard; but who could immediately grasp the advantages of house-to-house visitation to teach mothers how to care for babies? It took a long time to win general support for the work of a nurse as a health visitor; three-quarters of a century or more was to pass before the nation took the first positive step from a belief in the responsibility of the environment as a cause of ill health (something that only the State could remedy) towards an understanding of the equal responsibility of the individual which depended on a way of life within his own control. It has taken still longer to begin other work along similar lines, such as the preventive health work in relation to mental deficiency, lunacy, and venereal disease. It may yet be another hundred years before the possibilities of public health through individual teaching by skilled personnel have been fully exploited.

The 20th century has hitherto been devoted mainly to the development of personal health services to supplement the environmental health services of the 19th century. This second period of public health has resulted in services with which everyone is familiar—the maternity and child-welfare service, the tuberculosis service, the venereal-diseases service, and the school health service. At the root of all these services there are the ideas of detecting disease early enough to make treatment a preventive measure and of influencing susceptible individuals by bringing them into contact with personnel of preventive medicine. No service illustrate this better than the school health servi where teacher, doctor, and nurse can singly and joint bring their influences to bear on parent and child.

One of the great advances of this second period public health has been the development of health education, coupled with a greater understanding of the soc aspects of disease. Fifty years ago we laid stress the importance of pure water-supplies; today we con sider the unclean cook as dangerous as unclean wat The kitchen worker who infects food from fingers soil with fæces, or from the nose, can be as much a mena as the shallow well or the contaminated river wate supply. So also we taught fifty years ago, and s quite rightly teach today, that bad housing sprea tuberculosis; back-to-back houses can be shown to ha high incidences and death-rates from tubercul because of their poor ventilation and high concentrati of tuberculosis germs when the household includes open case of phthisis. But now we think it equal important to emphasise the personal responsibili of the individual sufferer; for we know that wi scrupulous personal hygiene even an open case need transmit his infection. In Papworth, where famili live with the infected father and mother, the infecti of children has been shown to be less than in the norm community.

The modern approach to health increasingly stress personal responsibility, and to this end health educati should include a knowledge of germs and how they spread, of physiology and how to apply it, and of biolo in its importance to the welfare of man.

FORMATION OF LINKS WITH CURATIVE MEDICINE

We may recognise, therefore, two periods of publ health—the first almost wholly environmental, t second environment and personal. There is also a thir During its first two periods public health developed almost complete isolation from curative medicin The third is the period when the weapons of curati medicine have been called more and more into the servi of preventive medicine: when the children's specialis perhaps a little reluctantly, has left his children's be to devote some of his time to the problems of the scho health and child-welfare services; when the orthopædi surgeons have wanted to go further back to see whethe their special knowledge and skill could not be of hel in preventing deformities; when the consultant obste trician has considered how to make his beds for materna abnormalities redundant. All hospital specialists hav much to give to preventive medicine, and there has been movement in this direction. This is the time of special diag nostic clinics—the clinic where the cases of handicappe children can be reviewed by the children's specialis so that parents and education authorities can be advi-e on the fullest knowledge available; the clinic for chil guidance, with the psychiatrist and educational psycho logist working together; the clinics for orthodontic for difficult problems of expectant mothers, and fo various disorders. Such special diagnostic clinics hav been valuable in combating venereal disease and tuber culosis. As we seek to tackle the degenerative disease they will be invaluable for the early detection of cancer arteriosclerosis, and diabetes.

As part of this same effort to harness curative medicin to preventive medicine, arrangements have been made fo doctors (and other personnel working in the preventiv field) to spend part of their time in hospitals; and equally important, the patient leaving hospital is bein handed over to the care of the health authority for after care when this is needed. The time when the hospital regarded itself as something apart from the life of the community is passing: it would be a matter of surprise if a weakly baby were to be discharged without ry as to unsatisfactory home conditions; yet only years ago it would have been thought unusual to any such inquiry, and many a baby has gone from oving care of a maternity home or hospital to die hovel. With the passage of the Education Act of hospitals began to supply school authorities with mation about children admitted. This made ble a new service of care and aftercare and enabled l health records to be complete in essential culars.

EASING COMPLEXITY OF PUBLIC-HEALTH PROBLEMS

blic health slowly commits suicide; for, as it is ssful, it progressively removes the reason for its being. But although society today is vastly different what it was when public health began, there is as no lack of work; all that has so far happened has ted only in a widening horizon and a shifting hasis.

blic health has changed society: it has changed its onstitution; it has abolished, speaking very broadly, tious disease; and it has removed the more obvious es of ill health and death. This has had a profound t on the practice of public health itself, which is increasingly concerned with the degenerative ases of middle life and late years, and with the of the aged. In England at least, the main battles nst the pandemic infections, such as smallpox ue, and cholera, have been won; and despite the ged resistance of their rearguard, chiefly the virus ctions of poliomyelitis and influenza, infections of orts are now fighting a losing war against an improv- environment, increasing education, and the weapons he laboratory. Even in the past fifty years tuber- sis has fallen from the position of chief killer with eath-rate of 190 per 100,000 to that of fourth on the with a death-rate of 55 per 100,000; pneumonia, ich in 1900 had a death-rate of 137, now takes a toll of ; diphtheria and scarlet fever have virtually ceased killing diseases.

But what is left of ill health and disease is generally re obscure and less easy to remedy. As an example, en Booth wrote in 1900 of the poor of London, and wntree of the conditions of York, these two sociologists ked about a "submerged tenth" of the population. fifty years this submerged tenth has disappeared and a mere 80,000 "problem families." But whereas main bulk of the submerged tenth was biologically nplete, and only awaiting, so to speak, the inspiration assistance of social services to raise themselves from pond to decent modes of life, the same cannot be said problem families, who, being biologically incomplete, not raise themselves unaided. Public health for e problem families will be much more difficult than ucing the infant mortality from 150 to 38.

It is because the residual problems of public health come more difficult that it becomes increasingly portant to secure that all types of medical specialist all give time and thought to preventive problems.

BENEFITS FROM THE ACT

What then has been the effect on public health of the ational Health Service Act, 1946, the greatest medical atute since the Act of 1858 which created the General edical Council and State registration of doctors? s third part enumerates the duties of a preventive haracter placed on the local health authorities. They ust, it says, provide a comprehensive ambulance rvice, carry out vaccination and immunisation, and uild health centres. They must also provide health itors and home nurses who, with home helps, should gain enable the general practitioner to undertake the are of many patients whom he now sends to hospital and who would be better nursed at home. It will take many years to build health centres if the cost of the first London centre (£186,000) is any guide; but when they do come about they may develop into centres of preventive medicine where adequate records and routine health checks become routine procedure; they are intended to combine the work of general practitioners with that of local-authority health clinics and at some time in the future they will become the focus of medicine. One omnibus section of the Act makes the authority responsible for preventing illness and for care and after-care—all these services are capable of great extension.

The removal of many responsibilities directly related to curative medicine is a substantial advantage to public health: the relief from executive charge of hospitals will give the medical officer of health more time to tackle the many aspects of public health which need closer attention. The tracing of tuberculosis contacts is an obvious example, for few can feel satisfied that our knowledge of the epidemiology of the disease has so far been put to the best advantage. In an ageing community the medical officer of health must play an increasingly important part in the welfare of the aged, surveying his area by means of his health visitors, home nurses, and sanitary inspectors, and seeking to remedy the appalling state into which many old people fall. The allied problem of home care of the chronic sick will also need his attention if we are to avoid big increases in hospital beds. With the conquest of infectious disease the emphasis of public health must inevitably shift towards the higher age-groups where the degenerative diseases, diabetes, cancer, arteriosclerosis, call for the same measure of interest as medical officers of health have in the past given to the acute infections of childhood and early adult life. This does not mean that the traditional fields of work in public health are no longer capable of occupying his time; in some at least—e.g., in the more intensive attack on infant mortality—the opportunities are expanding as our knowledge grows. Much can be done to prevent the infections of early life, prematurity, and no doubt many rarer infant disorders. And there are new opportunities for working with general practitioners for the care and aftercare of the patient at home.

Part III of the Act can, in fact, be regarded as a minor charter in public health. Had it been passed into law without the rest of the Act the world of public health might have acclaimed it without reservation. Nevertheless some unfortunate disadvantages arise from the new administrative structure.

FOCUS ON HOSPITALS

By its creation of separate authorities to handle treatment, largely under State control, the Act has placed a new emphasis on curative medicine. The work of hospitals and specialists has been put under the jurisdiction of 14 large regional hospital boards; and in the hands of these boards is now the virtual control of the development of medicine. The boards are non-elected, and of the members selected by the Minister about a third are doctors, almost all of whom come from the world of curative medicine. The boards are not charged with any duties to prevent disease, and they are certainly not constituted to show any natural interest in public health. A physician who tends the sick thinks in terms of the individual; public health thinks in terms of the community. This would have no great significance were it possible to separate curative and preventive medicine. But the separation is impossible.

In the latest phase of public health there has been an increasing use of the facilities of curative medicine—notably by the employment of hospital specialists within the preventive field, by the establishment of special diagnostic clinics, and by the use of institutions in support of preventive services. Preventive medicine had begun to harness curative medicine to serve its own *great ideal.* This may still be possible, but there is no denying that it has become vastly more difficult. In all his plans for health, from those designed for the care of premature babies delivered at home to those which may seek to reduce the degenerative diseases of the aged, the health officer is now dependent on another authority to provide either special beds, or special case-finding clinics, or special medical personnel to visit in the home.

Here, therefore, lies the difficulty for public health; to do its best work for the community it must have an equal right to certain of the assets of the regional hospital boards; it must have a voice in the use to which many institutions and specialists are put; and it no longer has such a voice.

Furthermore, public health was centring thought upon a healthy community of happy families; in this picture the hospital was regarded as a necessary evil to be done away with as soon as possible, and as a bad psychological influence, especially for children. All institutions were regarded as no more than part of the machinery with which to support the community life: maternity homes for those who cannot have a baby where a baby should be born—at home; sanatoria to take those men and women whose condition makes them a source of danger to the community. As an example, school health was centred on the school; eye-testing, dentistry, and diagnosis were presented to the children not as hospital events but as part of the normal process of keeping healthy and to be related to the teaching of positive health and hygiene in the schools. Today health services are being increasingly focused again on treatment and on the hospital. The school dental service is already giving ground before the onslaught of adult caries; the school ophthalmic service becomes a concern of the hospital; there is imminent danger that once again diagnosis may become associated with the outpatient department, and that pædiatricians, obstetricians, psychiatrists, and the whole world of specialist medicine may once again be absorbed into the hospital wards.

REGIONAL BOARDS OF HEALTH?

It is certain that an emphasis on health and on the community, and the full application of medical knowledge to the ills of society, will be harder to achieve within an administrative framework which has established large, powerful, State-supported boards to manage hospitals and specialists, and which leaves the management of health to the now relatively small authorities of local government deprived of many of their weapons. The regionalisation of curative medicine has swung the balance of power so violently towards curative medicine that many believe a similar regionalisation of public health to be the only means of solving the new problems with which it is faced.

Such a step would have serious implications. Local government, with its many gradations of size and variations in autonomy, has ministered well to the Englishman's aptitude for experiment, his desire for trial and error, and his empirical mind, particularly in the public-health field. Few can doubt that preventive medicine in England has reached its present high state of development mainly because authorities guided by medical men with a specialist training in preventive medicine—thinking and planning for the needs of society—have been financed by a local rate and have therefore been able to take the initiative. Today it is more than ever necessary that the specialist in community health shall be given a free hand to develop his art.

Another obstacle which will have to be overcome, if public health is separated from local government as we now know it, arises from its close relation with other social services, such as housing and No doubt these difficulties could be met by the necessary public-health advice to local under a scheme of divisional administration. greater difficulty would be encountered in the s health service, which is an integral part of the educ service; but even this difficulty could be over The school health service must remain part of the system, and it would be necessary to resist strongl suggestion that some inspection, somewhere else a some other manner, could be substituted for it. would be attended by grave disadvantages; the g of *School and Life*[1] is I believe irrefutable— teacher, school nurse, school doctor, school child, parent in conclave, if necessary, together. Accord the work must be done on school premises, in school and by school doctors who give their time without commitments. Special schools for delicate, deaf, and other handicapped children should remain wit education committee. With this principle securely the school health service could be retained as an int part of public health, from which it has so much to and could be regionalised with the rest of public he

Some will say that the remaining health func should be transferred to the regional boards. Bu outlook of the clinician, who occupies more than a of the seats on the boards, is centred upon the indivi even when he is imbued with the new spirit of medicine. The outlook of the medical officer of h centres upon society. If then local government in he after a glorious reign, is now to be deposed, let no throne be occupied by those who know not. Let be a complete recasting of the administrative fr work. If this is to be centred on regional areas, let be new authorities, locally elected and with the inc able advantage of a local rate, and let them have a me officer of health with equal power to speak his mi official reports and in public writing and with dutie responsibilities in no way subordinated to curative med

Such an arrangement would have to meet the cri that there would be two separate authorities dealing medical matters in each region. It is impossib deny the force of the argument that the health ser demand a unified administration if they are to b economic proposition, and it is a fair inference that unification is now possible only at regional level. N theless, there are powerful reasons why the pr regional boards are not suitable organs for such a u control. Chief among these is the fact that reg boards are chiefly concerned with the cure of sick in hospital; if, with their present constitution, were to absorb the preventive services it is likely public health would suffer.

TOMORROW

The only type of hospital which has so far been almost wholly redundant—the first I hope of ma is the fever hospital, the creation of the medical o of health. As we work we continually remove causes for our own employment and that of the auxili of our own creation. But to argue that the me officer of health is no longer needed is blind complac It presumes that society could not retrogress, as it that society is now so perfect that it cannot adv This is nonsense. There are plagues enough still wit What of the degenerative diseases—*cancer*, art sclerosis, diabetes—which take an *increasing* Old age has still to be made a healthy, happy, useful period of life. What of the hospitals themse and the crowded outpatient departments? What of and the infants who still die uselessly *to the shame of* a mo society? What of the problem families and the hom

ren, and the smoke and slums which still mock our ts to create a healthy community of healthy families? me time the day will dawn when society no longer s the medical officer of health, but until that day s it behoves this country to fight for his preservation free agent. To give him his proper place in the new r of things he must be accorded specialist status, his training must be of the same order as that of the ee specialists under the Spens report: five years spent following graduation, included a year's diploma cial medicine, equipped with the new disciplines ated by Crew and others, and expanded to cover the e of man's ills as outlined by Ryle: a year to be t in some special study related to social medicine. n a department of physiology or an institute of itional research; a year to be spent in an executive rtment of public health: and a year in study ad.

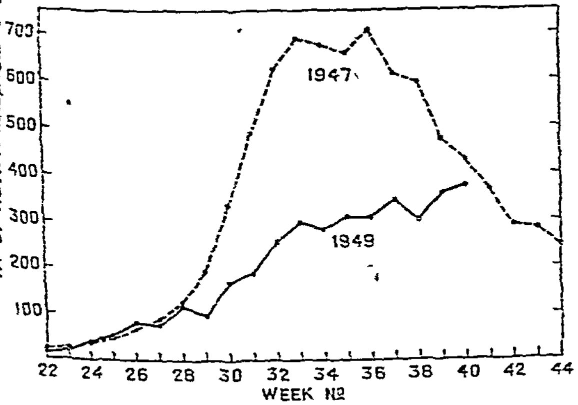
trust that the ideal of "public health" will be erved and not lost in a glorification of curative icine. With its help England might yet progress society as far removed from that of today as ours is rent from the time when Southwood Smith and Lord ftesbury walked together in the slums of Bethnal en.

Vaccination Reminders

n Canterbury all parents receive a notice about cination as soon as their child's birth is notified. s contains a short explanation of the reasons for cination at about 3 months, and the parents are asked fill in and sign either the brief request form addressed their own doctor or the attached postcard requesting M.O.H. to arrange for vaccination at the immunisation tre. A further notice, headed "A Second Thought on ccination," is sent if the child is still unvaccinated en 3 months old.

Poliomyelitis

During the week ended Oct. 8 notifications in England d Wales were: poliomyelitis 340 (331), polio- cephalitis 34 (26). High prevalence is being prolonged s year beyond the usual time, and first cases this r were reported from Anglesey and Radnor.



The following counties reported multiple cases (polio- myelitis and polioencephalitis together): London 52 (44), Bedford 5 (5), Berkshire 6 (5), Buckingham 2 (2), Cambridge 3 (0), Chester 5 (4), Cornwall 2 (8), Devon 3 (1), Dorset 7 (5), Durham 2 (3), Essex 31 (26), Gloucester 23 (17), Hertford 4 (12), Kent 26 (19), Lancaster 24 (41), Leicester 4 (2), Lincs, Lindsey 6 (8), Middlesex 30 (18), Norfolk 1 (4), Northampton 4 (4), Northumberland 6 (0), Nottingham 8 (9), Salop 2 (0), Somerset 6 (6), Southampton 4 (7), Suffolk, East 4 (2), Surrey 9 (9), Sussex, East 2 (5), Warwick 19 (13), Westmorland 2 (0), Wiltshire 4 (8), Yorks, East Riding 2 (3), Yorks, North Riding 3 (2), Yorks, West Riding 50 (38), Glamorgan 7 (6).

WORLD MEDICAL ASSOCIATION

MEETING IN LONDON

MEDICAL ethics, postgraduate education, and social security were among the chief topics discussed at the three-day meeting of the general assembly of the World Medical Association in London last week. Delegates from the following member countries attended: Australia, Austria, Belgium, Canada, Colombia, Cuba, Denmark, Eire, Finland, France, Great Britain, Greece, Iceland, India, Italy, Luxembourg, Netherlands, Norway, Pakistan, Peru, Philippines, Portugal, South Africa, Spain, Sweden, Switzerland, Turkey, and the U.S.A.

The election of Dr. CHARLES HILL as president for 1949–50 was unanimously confirmed, and he was inducted by Prof. EUGÈNE MARQUIS, the retiring president.

Membership of the association is open to national organisations of doctors, and the assembly admitted two new members—the Asociacion Medica Nacional (Panama) and the Colegio Medico de el Salvador.

FINANCE

Dr. O. LEUCH (Switzerland), the treasurer, announced that the council had decided that for next year members in the sterling area should pay their annual subscriptions at the same level in their own currency as if there had been no devaluation. It was not possible to recommend any reduction of annual subscriptions, for the regular income from subscriptions amounted to less than one-tenth of the expenditure of the United States committee, and income from this source had been guaranteed only until 1952.

The United States committee raises funds for the running expenses of the W.M.A., financial contributions being made to it by medical organisations and other bodies, and by individuals; of the $54,419 contributed to the committee in the first half of this year, $12,000 came from individual doctors in the U.S.A.—an indication of the interest taken by them in the world organisation. The assembly passed a unanimous vote of thanks to the United States committee, the American Medical Association, and the American doctors who had contributed to the association.

COUNCIL'S REPORT

In presenting the report of council, Dr. T. C. ROUTLEY, its chairman, explained that the association did not direct national associations as to what they should do, but sent to them all available information. On the position of refugee doctors, Dr. Routley said these had been accepted by two countries.

The council was unable to see that any useful purpose would be served by affiliation to the World Union of Medical Science. In regard to UNESCO, the World Health Organisation, and similar bodies, however, the W.M.A. was "what electric power is to transmission lines." Dr. Routley said that in proposing a conference on the coordination of scientific medical organisations, the council had no desire to overlap with UNESCO, with whom relations were cordial. The assembly agreed to this recommendation by council, and also to inquiries into pharmaceutical practices and hospitals. The assembly also approved a suggestion from Dr. O. RASMUSSEN (Denmark) that the supplementary investigation into the status of the medical profession should include a study of its economic status and a comparison with that of other professional people.

Though the association has been in existence for three years, until now it has had no emblem of its own. This was rectified by the assembly, which approved an emblem in blue and white, consisting of a globe with staff and serpent superimposed at an angle.

REGIONAL REPORTS

The report of Dr. S. C. SEN (India), assistant secretary for Asia, referred to the agitation for recognition by practitioners of such indigenous systems of medicine as Ayurveda and Unani. It was to be hoped that ultimately all medical practitioners would possess the same basic qualifications; but at present, because of the shortage of money and medical personnel, the government felt inclined to use the services of these other classes of practitioners.

Dr. PAUL CIBRIE, assistant secretary for Europe, reported that the council had approved a questionary to be sent to all medical associations for the purpose of inquiring into the peace-time activities of the Red Cross, some of which, it was felt, infringed on the medical profession at large and should be opposed.

MEDICAL ETHICS

The main discussion at the first day of the assembly was on the proposed code of medical ethics, drawn up by a committee presided over by Dr. Cibrie and intended as an amplification of the Declaration of Geneva—the new version of the Hippocratic Oath adopted last year.

Dr. P. MORAN (Eire) objected to the first paragraph under "Duties of Doctors to the Sick":

> "A doctor must always bear in mind the importance of preserving human life from the time of conception. Therapeutic abortion may only be performed if the conscience of the doctor and the national laws permit."

Dr. Moran moved to leave out the last sentence, declaring it to be an abrogation of the fifth commandment.

Dr. CIBRIE pointed out that only very severe conditions would permit of therapeutic abortion. Should any country feel that this sentence should be struck out the W.M.A. would not object.

Dr. F. SONDERVORST (Belgium) thought it unwise to include this sentence in a code of ethics; a physician might get behind the article to procure abortions.

Dr. J. A. PRIDHAM said that murder could be committed by action-deed or by action-omission. "If a doctor is certain, and his colleagues are certain," said Dr. Pridham, "that the mother will die unless the pregnancy is ended, and he allows that pregnancy to go on, might he not be thought to have committed murder?"

Dr. L. LLEWELLIN DAVEY (Australia) felt that the sentence was badly worded. He would substitute the words: "Therapeutic abortion may only be performed if the welfare of the mother demands it." That would have to be decided in consultation with other doctors.

Prof. K. FELLINGER (Austria) held that the purpose of a code of ethics was to declare principles, and if an exception was made the principle was weakened. Dr. L. DE CAMPOS (Portugal) thought that to base a code of ethics on national laws was very dangerous for the profession and for the individual physician. Dr. MORAN said that in so-called "therapeutic" abortion the doctor took active steps to kill, whereas if the pregnancy were allowed to proceed the mother might recover. He thought that the very thing they wanted to avoid was that the mother should decide.

The amendment was defeated by 22 votes to 19, but it was decided that since the margin was so narrow a small committee should be set up to find an acceptable common formula. The effect of the committee's recommendation, agreed to next day by the assembly, was to drop the controversial sentence, substituting for the whole paragraph the words:

> "A doctor must always bear in mind the importance of preserving human life from conception until death."

The code of ethics, as amended and adopted by assembly, lays down that the doctor must always tain the highest standards of professional conduct. must not allow himself to be influenced merely of profit. The following practices are listed as any self-advertisement, except such as is authorised the national code of medical ethics; taking part in plan of medical care in which the doctor does not professional independence; and receiving any other than a proper professional fee, or paying money in the same circumstances without the of the patient. Under no circumstances is a permitted to do anything that would weaken the or mental resistance of a human being, except for therapeutic or prophylactic indications, imposed in interest of the patient. A doctor is advised to use caution in publishing discoveries, and when called to give evidence or a certificate he should state that which he can certify.

A doctor must always bear in mind the importance preserving human life from conception until death. owes to his patient complete loyalty and all the resou of his science, and where necessary should summ another doctor. He owes his patient absolute secr on all which has been confided to him or which he kn because of the confidence entrusted to him. A doc must give the necessary treatment in emergency, un he is assured that it can and will be given by oth The code concludes by setting out the following du of doctors to one another: A doctor "ought to beh to his colleagues as he would have them behave to him he must not entice patients; and he must observe principles of the Declaration of Geneva.

It was agreed to leave it to national medical asso tions to modify the wording of the international code medical ethics for use within their countries, provi that it conformed to the principles of the code.

GENERAL PRACTITIONER AND SPECIALIST

On the second day Dr. R. L. SENSENICH (U.S. reported that the committee on standards of medi care and allied subjects, of which he is chairman, considering the best method of obtaining informati on undergraduate medical education. The idea was be objective, not critical. The report was adopted.

The committee on postgraduate medical educati and specialist training presented a bulky docume containing data on postgraduate facilities from answ to questionaries returned by 32 national medical associ tions. The report noted how Great Britain and t U.S.A. are the countries to which doctors of oth nations mainly turn for postgraduate studies, and th doctors in these countries do not often go abroad postgraduate work. In Cuba and Eire the length training required for specialisation is less than a yea some other countries insist on five or six years. In t Dominican Republic and in Italy postgraduate educati for general practitioners is compulsory. The committ defined "consultant," "specialist," and "general prac tioner" as follows:

> A *consultant* is a medical practitioner whom his colleagu recognise as one worthy to be called in for advice and opin by virtue of his special knowledge and experience.
>
> A *specialist* practises in one or more particular fields medicine and is often a master of some special techniq
>
> A *general practitioner* is a family doctor.

Dr. PRIDHAM, chairman of the committee, declared "The matter of postgraduate work is one which, than goodness, the profession still holds in its power and not subject to government interference." It was specially appropriate subject for the World Medic Association.

e investigation, he said, had shown that the level of raduate education and the facilities for it differed y throughout the world. The committee felt that country should arrange facilities for the inter- ge of students, to raise standards throughout the world. Secondly, the report drew attention to ecessity for continuing the education of the general itioner and emphasised his importance in any ne of medical care. In some countries there was y a fear that the general practitioner might be zed out or his importance lost sight of, and that rge a proportion of young men on qualifying might to become specialists. "In my own country." Dr. Pridham, "the emoluments and remunerations d to the specialist, and possibly the easier life which possible for them, are bound to attract younger to attempt to enter the ranks of the specialists. hall have to guard against this tendency."

of. A. P. **CAWADIAS** (Greece) felt that in the future pecialist would be the consultant; with the advance nowledge the general consultant was disappearing. ssor Cawadias also spoke of the importance of a r having a good level of general culture, which was ed upon in the entrance examinations to Greek ersities. General culture was even more important the specialist than for the general practitioner; something should be done, as in Greece, for the alist to show that he had that culture.

. **CIBRIE** (France) disagreed with Professor Cawadias his last point. The general practitioner should not egarded as at the bottom of the ladder and the ialist at the top. Dr. **SONDERVORST** thought that the for physicians attending postgraduate courses should be paid by the State but by the doctor himself or ugh grants or fellowships.

r. **SEN** deplored the tendency for the specialist to k of himself as on a higher plane; the general titioner was equal, if not superior, to the specialist. many countries the period of training for specialists being extended further and further; in Austria as now six years. Medical education was already ciently extensive; and time and expense should borne in mind. In establishing schools for general titioners or specialists, emphasis should be laid on imum and not on maximum standards. "We did have all that long and expensive education which are insisting on for others." The difficulty about ure, Dr. Sen continued, was in defining what was nt by it. It seemed that to have culture one needed h leisure and money. In India the highest definition ulture was "tolerance." Culture could be obtained n study, not only of Greek and Latin, but also of the ient languages of the East.

r. **MORRIS FISHBEIN** (U.S.A.) suggested that it would an error to establish general-practitioner hospitals distinct from hospitals in which the general practi- ler and specialist both worked. Where a State medical rice was in operation there was a tendency to relegate general practitioner to second place—he became a on who merely referred cases to a specialist. In the A. the trend was towards giving the general practi- ler greater opportunities for the care of cases which merly went to the specialist. This was the effect of ances in medicine; in otolaryngology there was le left for the specialist except fenestration. Dr. hbein called for complete integration of the general ctitioner into the hospital service, with adequate resentation on the hospital staff and executive mittee.

Professor **FELLINGER** declared that medicine was ending and it was very important that the doctor's cation should also be extended. In Austria not only l the length of the specialist's training been extended six years, but three years' hospital experience was now necessary before a general practitioner could practise. Dr. **DAG KNUTSON** (Sweden) believed that it was perhaps more important for the general practitioner to be cultured than it was for the specialist. It was a great danger that not only were general practitioners looked down on, but they tended to look down on themselves. The problem was related to the economic factor; if conditions for the general practitioner were not good, and were far less good than for the specialist, he would be looked down on. In Sweden, the general practitioner was referred to as a specialist. This raised him in his own eyes, as well as in the eyes of the world.

Dr. **W. CLINE** (U.S.A.) moved an amendment to the report, to read:

> "Individual hospitals should welcome visits from general practitioners. Posts should be made available to them. Such posts are of benefit both to the specialist and the general practitioner. There should be general practitioner beds in ordinary hospitals and the general practitioner should be integrated into the hospitals. In this manner the general practitioner will become a better doctor and have more interest in his work."

Professor **FELLINGER** and others said that in European continental hospitals there was a different system of allocating beds, and here the proposal would not be practicable. It was agreed, therefore, to add the words "where possible," and the amendment was carried. Dr. **PRIDHAM** pointed out that doctors from all over the world, most of whom were themselves specialists, had emphasised that the division between specialist and general practitioner was too wide.

The assembly approved recommendations that after the medical-school course there should be an additional period of training "in an approved post," before engaging in independent practice; and that a specialist should be required to obtain adequate theoretical and practical postgraduate training. It also called on national medical associations to develop arrangements whereby postgraduate studies and practical experience would become available to members of the profession in other countries. Dr. H. **GUY DAIN** mentioned that in Great Britain the new Medical Bill would allow foreign graduates coming to this country for further studies to have their names placed temporarily on the Medical Register so that they could take charge of patients and thus gain experience.

PUBLICITY

Dr. **FISHBEIN**, presenting the report of the committee on ways and means of securing publicity, observed that medicine no longer functioned in a vacuum; and it was important that doctors and the general public should be aware of the assembly's activities.

The **PRESIDENT** reported that the council had appointed a committee on standard nomenclature.

The assembly considered in a somewhat critical mood the activities of other international organisations and the association's relation to these organisations.

ELECTION OF OFFICERS

The last day was devoted to a discussion on social-security schemes as they affect medicine; but first the assembly unanimously elected Dr. E. L. Henderson (U.S.A.) as president-elect for next year; Dr. Henderson is president-elect of the American Medical Association. The following retiring members of council were re-elected: Dr. Cibrie, Dr. Knutson, and Dr. Pridham.

SOCIAL-SECURITY SCHEMES

Dr. **ROUTLEY** (Canada) took the chair for the discussion on social security, which was opened by Dr. **HILL**, who presided over the committee which had drawn up a report for the assembly. This report, which comprised a factual survey of the social-security schemes in different countries and their effect on the medical profession, stated:

> "In many countries at present medicine is faced with two sources of danger to its freedom—by non-medical insurance bodies and by governments. The danger from the first lies in the attempt to subordinate medical service to the conservation of financial resources by subjecting the doctor and his services to non-medical control. The danger from the second lies in the possible transformation of the doctor into a civil servant."

Dr. Hill declared that this problem confronted member associations of the W.M.A. all over the world. "Wherever schemes of social security embodying schemes of medical service are being evolved," he said, "the medical profession is being presented with the problem of preserving, not only in the interests of the profession but also in the interests of the public, the essential freedoms of the medical profession in the conduct of its work." It was essential that the medical profession should exchange facts about what was happening in the different countries; for governments were closely associated among themselves in this matter, and "information passes from government to government as swiftly as rumour passes around a mothers' meeting." The association had good relations with the W.H.O., but there was equal need for vigilance and scrutiny of what governments were doing in the international field.

In the debate, delegates described experiences in their States. The first speaker was Dr. **Dain**, who criticised the sudden introduction of a complete medical service in Great Britain. "The Minister believes in the method of learning to swim by throwing you in and seeing what happens," commented Dr. Dain. In this case the inevitable had happened. Doctors were overworked; there were insufficient hospital beds and nurses; and the demand for free material had greatly exceeded the estimated demand. All that could have been foreseen. The position of the medical profession was very difficult. The remuneration of the general practitioner was even yet not settled, fifteen months after the scheme began, and it was only within the past few weeks that specialists and consultants had known what remuneration they would receive. Freedom for the patient to choose his doctor, and for the doctor to choose where he should practise (provided it was not an over-doctored area) and to practise the system of medicine which he preferred, had been secured. But Dr. Dain criticised the refusal of the Government to allow the private patient to obtain drugs under the scheme, and the establishment of a virtual State monopoly of hospitals; and he suggested that the few hospitals which were exempted could form the beginning of a second hospital service outside the State. The system of payment of general practitioners by capitation fee prevented doctors from becoming civil servants and gave them freedom to criticise the service. The rush of work had made many doctors complain that they were not able to give the attention to each patient which they would have liked, but he hoped this was merely a temporary phase. In hospitals the effect of the change-over from honorary to paid service had not yet been good; because they were paid by sessions, surgeons and physicians tended to work in sessions, but Dr. Dain thought that they would recover from this. He believed that the heartburning over status could have been avoided if posts and not persons had been graded. "These," concluded Dr. Dain, "are the sort of teething troubles that we have suffered from in the first year. I may say for the B.M.A. that we are the fathers and the grandfathers of the idea of a State service. We are determined to do our best to see that the State service in this country is ultimately the best possible. We have some journey to go before we succeed in attaining our ambition, but it is our ambition to make it work."

Dr. **Cibrie** declared: "If we get everything for nothing all the time, we will not be free any more." The provision of the best medical care for all was the aim of the W.M.A.; for this it was necessary to raise standards and to fight for the liberties of the profession. " afraid that through payment by the capitation physician was placed at the mercy of the patient. France and Belgium payment was made acc the actual visit or treatment. But each medical pr should decide this point for itself. Under no c stances, however, should the doctor be made a servant of the State.

Dr. P. **Glorieux** (Belgium) described how a medi service scheme had been imposed in his country wit any consultation, their minister of health, like others, taking the attitude: "I act first; thin comes afterwards." The doctors had had to obstruct administrative machine to get representation. The committee recommended a scheme acceptable to all, no changes were made. Now the government found cost so heavy that the nation could not bear it, an had set up a new commission to reconsider the w matter. But even on this commission there was representation of the doctors.

Dr. W. **Magner** described the steps being taken wit view to establishing a full measure of health insur in Canada. The Canadian Medical Association, he would oppose any Act, on the British model, ve professional control of doctors in the hands of one —the minister of health. It recognised that advance medicine had greatly increased the complexity and c of medical services, and so led to inequalities. It thou that this could best be overcome by extension of vol tary insurance schemes, with government subsidies those in the lower-income groups.

Dr. **Knutson** said that everyone in Sweden always been able to obtain the very best medical c regardless of their means. Yet there had now been forward proposals for comprehensive compulsory in ance to cover every form of medical care, preventive well as therapeutic; to make all doctors full-time c servants; to regulate the doctors to work 7 hours a d the general office-hours in Sweden; and to create hea centres. As a first step, it was proposed to set doct fees at 5s. for the first visit and 3s. for the second subsequent visits, regardless of whether the doctor a general practitioner or a specialist, or of the nat of the treatment given. Those who put forward the proposals did not mention the cost. It had been diffic for the Swedish Medical Association to estimate expense, because the wording was hazy, but it calculat that the initial cost would be more than £70 million, wi an annual cost of £50–55 million, as opposed to £30- million being spent at present. Taxes in Sweden we already at a forbidding height. The Swedish Medic Association held that the freedom of doctor and patie was seriously threatened by these proposals. Instea the position should be dealt with by helping with tra port arrangements (an important factor in Sweden by encouraging and extending voluntary schemes; augmenting the technical facilities at the disposal the general practitioner; and by arranging for postgraduate education.

Dr. **Llewellin Davey** reported that the aim of Australian government was to socialise and regim doctors, and it hoped to bring about a cessation private practice. A start had been made with Pharmaceutical Services Act, which was regarded doctors as the "thin end of the wedge" of control. T Act had now been largely dropped. Three princip that the federal council of the B.M.A. in Austral thought essential were: payment by the refund syst exclusively (the patient paying the doctor and collecti the money back); a scale of benefits and not of fe and no experimental health centres.

Dr. J. H. **Harvey Pirie** instanced the suspension the free hospitalisation and medical-services scheme the Transvaal as an example of what the me profession could do if it organised itself and fo

SEN said that a committee had recommended that 0 years India should have complete social security, e prime minister had lately declared that India be a welfare State. But at the moment funds isufficient.

G. MOUTHON emphasised the need for a constructive e. In France the medical profession was trying perate with the government to evolve a scheme would be satisfactory to those who wanted a service , infringe upon the rights of the medical profession.

CLINE explained that in the U.S.A., with its vast nd diverse population, any national comprehensive would be beset with difficulties. The American d Association desired the best medical care for all, lieved that this could best be achieved by ensuring te freedom for doctors. It was therefore pressing largement of the voluntary insurance schemes. als were before Congress which would confer powers to those vested in the British Minister of Health ; any of these proposals were indeed lifted straight he British scheme. This was regarded as a purely atching move by people who were not primarily sted in health. The A.M.A. felt that compulsory insurance was the thin end of the wedge. "We are sed and we are determined to fight," said Dr. Cline.

HARVEIAN FESTIVAL

St. Luke's Day, Oct. 18, Dr. GEOFFREY MARSHALL red the Harveian oration to the Royal College of cians of London. His subject was Individuality dicine, to which Harvey's own independence of offered an appropriate opening. Like us, Harvey in disturbed times, and then as now, Dr. Marshall rapid changes in the relationship of the individual the State were not accomplished without some ice and resentment. When Harvey practised, and Thomas's were the only hospitals open in on, for many old foundations had been closed g Henry VIII's persecution of the religious foundawith which they were associated, "so that they t be brought into decent and convenient order, h the King would not suffer poor and miserable e to go unrelieved." Did we even now today times catch an echo of this Tudor propaganda ? in the 18th century came the renaissance of the itary hospitals. In form and purpose they were se, but they had common traditions of service their freedom from central authority gave them iduality.

en in due course the Dawson report of 1920 was figured into the Bevan plan, some of us (Dr. hall continued) suggested that insufficient attention being given to individualism. The reply was always Government money would be used and that he paid the piper called the tune. But we were all ng the piper and we often called different tunes: there was only one piper: he had not the music ome of the tunes; and so he tended to play the tune h came most easily and which suited his pipe. the whole, Dr. Marshall thought, the traditions of eaching hospitals had been respected, but some other itals had fared less well. We heard of hospitals g closed, the character of others was changed, 50,000 were out of service, there were rumours of standardon of design of instruments and of preparations. were here, the orator ended, to help and not to ler, but it was right that we should call attention he inadvisability of destroying the will of the individual erve the community, and we must foster freedom diversity rather than standardisation and conformity. he service was to succeed, Government departments t absorb something of the sense of urgency and of onal responsibility of the old voluntary hospitals. y must not enmesh people in a web of restrictions. l they should remember that a multiplicity of mittees could be a hindrance to those who healed sick.

t the close of the oration Lord Moran, the president nted the Moxon medal to Dr. N. Hamilton Fairley for his work on blood pigments and on malaria.

In England Now

A Running Commentary by Peripatetic Correspondents

SECRETARIES came into their own at the meetings of the World Medical Association. The chairman of council is, in his other sphere, general secretary of the Canadian Medical Association, while the president has previously lived a quiet Jekyll and Hyde existence as the Radio Doctor and secretary of the B.M.A. It was sad that the fortunes of war prevented the general secretary of the Chinese Medical Association from attending to see in action the gavel which his association presented to the W.M.A. Unlike the intimidating "*Bang !*" of the ordinary Western gavel, this made a more subtle "*Plop !*" each time the president wielded it. The letter from Dr. John Yui which accompanied the gift explained that the gavel was made in the shape of a fish because it was believed that the fish always keeps vigil, "and thus it is carved in wood as a beating instrument to arouse people from idleness and slumber."

Looking round the assembly of delegates from nearly every part of the globe, I was struck by how alike doctors look. True, the Australian delegate was sunburnt, the Spanish-speaking ones had well-oiled black hair (though one of them, from South America, was a Dr. O'Leary), and only the Belgian delegate wore a black coat and striped trousers: and while many favoured pipes, the Danes came from a country where cigars are the normal smoke: but you would have picked out each as a doctor anywhere. The only startling splash of glamour came from the young Spanish interpreter, who not only wore a different dress every day but had sometimes changed her morning one by the afternoon.

Apart from the president, the only speakers who relieved the sometimes rather heavy debates with a sparkle of humour were Dr. R. C. Sen, of India, and Dr. Morris Fishbein, editor of the *J. Amer. med. Ass.*, and also of the trilingual *Bulletin* of the W.M.A. Illustrating his difficulties with the latter, Dr. Fishbein said that the Spanish text seemed always 15% longer than the French and English, and a French translator produced one version on manuscript, then altered it all on galley, and wanted to repeat the process when the page-proofs arrived. As a general example of how one may translate the same thing in various ways, he told of the obstetrician who wanted a motto to put (for some unknown reason) over the door of his new delivery-room. He finally thought *Primum non nocere* would suit. But he wanted to make sure, so he took it to the professor of classics at Harvard, who said it did mean "Do no harm," but it also meant: "Don't be naughty in the first place." This rather worried the obstetrician, so he went to the professor of classics at North-Western University, who confirmed both translations but gave as an additional meaning: "There is no harm in doing it once."

One used to think that if all spoke English it would be much simpler; now, of course, we know it only makes matters worse. Dr. Fishbein said that when he went over an English hospital—the delegates visited Barts on the Monday—he found that what he called a "food cart" was a "trolley," which in American meant a street-car. He bemoaned that we call a thing a "lift" when he calls it an "elevator" and the only kind of elevator we know is the instrument for raising the periosteum. For my part, I rushed out to get the pen of my aunt to write this.

* * *

We sat down to luncheon in the mental hospital with our Scandinavian hosts. The first course was "smorrebrod," just as my globe-trotting friend at home had assured me it would be. The charming lady doctor next to me repeatedly and persuasively offered me more. But I politely and firmly refused, though I had only touched a morsel: for had not my friend warned me that this was only hors d'œuvre, soon to be followed by more solid fare ? But for his advice I might easily have been deceived, for smorrebrod is a veritable *olla podrida*: pickled herring, smoked salmon, egg, cucumber, ham, tomato, sardines in tomato sauce, radishes, boar's head (I think), beef (I hope), horse (I fear), &c., &c., &c. Suddenly we all rose from the table, and I found to my consternation that the meal was over, and I had to urge my collapsing frame on an end[illegible] through the long passages, wards, and [illegible] stitution until the next feed six weary hours later. *Experientia docet.* So next day, having fortified myself with an enormous late breakfast, I knew just what to do at this hospital lunch. Boy, did I make that smorrebrod look silly—all 57 varieties of it! But was I dreaming? I was at once brought a plate of thick vegetable soup containing a poached egg. Before I could protest, which *took time* as I had to look up each word in my pocket dictionary, the waiter had brought me another plate of the same. This was followed by half a spring chicken with vegetables to match, then the other half, then a sweet, then an ice, and then a pause to smoke a cigarette and toast each other in schnapps. And then we began the whole business over again. How did I feel this time, and how did I stagger over the equally long passages, wards, and grounds? The gastronomic exertions expected of us in foreign parts are indeed formidable to the visitor from austere England.

* * *

My Irish colleagues and I spent the afternoon being conducted round Linnæus's house and garden. We followed this by suitable celebration. Proceedings livened up in the train back with "Give us a song Michael, before the dhrink dies in yez." So we all sang, except the dour Scot in the corner who tried to look as if he did not belong to our party. But the journey was long, the dhrink died in us, and as sleep overtook us I heard two voices: "Why, before this afternoon, Pat, Oi'd never even heard of Linnæus." "Shure, Molly, and had ye not? And wasn't it himself that invented the stethoscope?"

* * *

Like many of your seriously minded readers, on Saturday mornings I always turn first to "In England Now." Today I opened my *Lancet* at page 712, and being at breakfast folded the copy back to keep it out of the margarine, so I did not and could not see page 713. As I enjoyed the first two items, I had a counter-current of thought. "No-one ever seems to write about dreams in I.E.N." I said to myself. "There is a fine scope for speculative wit and humorous incident in that direction. Must scribble out something about these funny compression dreams of mine." Then I turned the page to find that another Peripatetic had done just that. Now this seems more than a simple coincidence; indeed, it looks to be a pretty fair example of the precognition phenomena described by Dunne in his *Experiment with Time.* I have had several experiences of the kind before, but this is one of the best because of the agreement on several points. But when these incidents do occur why are they almost always so trivial?

* * *

Who, I wonder, was the disingenuous fellow who first persuaded us that tobacco would not grow in this country? Some crafty chap, I suspect, with a packet invested in the American Colonies. In point of fact, of course, the stuff grows here like the weed it is. There are two beds of it in my garden, the result of sowing a thimbleful of dust-like seed, and I am hard put to it to find time to cut and string the leaves ready for drying; but the prospect of smoking 25 lb. of the stuff at fourpence an ounce keeps me wonderfully cheerful.

* * *

We're a little bit late
With the news in Kuwait,
But it seems strange to me
That sugar in tea
Thrown into a pot,
As likely as not
Kept under the bed,
Can turn Fehling's solution from blue into red.

*** Our peripatetic correspondent of Sept. 10 (p. 487) replies: "Blast! I should have asked Mrs. Brown whether her lodger took dextrose, lævulose, mannitose, lactose, galactose, aribinose, pyrocatechin, hydroquinone, or salicylates in his tea."

Letters to the Editor

SEEING THE PATIENT THROUGH

SIR,—Will you allow me to thank your correspond for their letters on this theme? They have done valuable underlining and suggested new aspects unlimited topic.

Professor Witts (Sept. 24) hunted in vain for almoners. He will find them taking part in a conference half-way down column 4; but I grant the brevity of the reference may have hidden my viction of their immense importance in any hospital coördination. We can be grateful for description of their highly developed function in his unit. Mr. Roy Goulding has sought to define a p for the student in the dealings between patient hospital; I am certain that the systematic weekly w round he suggests is the right way to keep him with his patients' progress—in order that he may ans their questions sensibly—and of emphasising the patie identity as something more than a teaching case.

Two main issues have crystallised out of this cor spondence; first, the internal hospital organis for seeing the patient through, with which I conce myself particularly in my paper; secondly, what may call the hospital-doctor relationship.

I believe that the machinery for seeing the pati through hospital is usually in existence, although it often faltering for lack of drive or creaking for lack lubrication. Miss G. L. John, medical records offi to the Bermondsey and Southwark Hospital Man ment Committee, a "specialist in coördination," (Sept. gives an alarmingly comprehensive account of her fu tions; she slides her tentacles around hospital dep ments like a well-meaning octopus and I feel that w her work is finished not only the "absent-mind leave-taking houseman" (who will take this descrip to heart, no doubt!) but the rest of the medical st also will be able to go on indefinite furlough. No; t agencies are already there, under the control of hous governor or medical superintendent, and I fear that the long run the coördinator will sap *rather* th stimulate their initiative; voluntary and sustain concentration on the welfare of the patient by each agen is a much better recipe.

Lastly, the hospital-doctor relationship. To my mi the most valuable letters in the correspondence have com from general practitioners; I am particularly indebte to Dr. Lindsey W. Batten (Oct. 1) and agree with ever word he writes. This is really the crux, that *it is th patient's doctor and not the hospital who must see hi through.* With the present hierarchical system medicine in which the technical rules supreme, the is a tendency for the hospital to skim the cream off gene practice and monopolise all that is important interesting. This process *must* be reversed if gene practice is not to be impoverished; *the hospital m* emulate the best standards of consultant practice taking infinite pains over the patient and feeding hi back to his doctor with a garnish of helpful informati and advice.

Taking infinite pains is the only possible formul In the midst of many medical frustrations it is a guid to the lasting satisfaction of seeing the patient through

J. M. LIPSCOMB.

St. George's Hospital, London, W.1.

PENTAMETHONIUM BROMIDE

SIR,—Pentamethonium bromide is at present under a shadow in the anæsthetic world because of *side-effects* which the physician may be able to use.

A substantially fit woman of 47 had a cholecystectomy under anæsthesia with thiopentone, nitrous oxide and oxygen 40%, and decamethonium iodide. During $1^3/_4$ hours she had doses of decamethonium iodide 5, 4, and 3 mg., each cing at least momentary respiratory arrest which was ed by normal recovery. At the end of the operation was slight respiratory depression from the last dose and resolved to test the effect of pentamethonium bromide uch 20 mg. was given and then after two minutes a r 20 mg. The pulse-volume decreased slightly, but ation was abolished after a further three minutes he total volume after one hour was still only 100 ml.

vas then suggested that she might be a submyasthenic hat pentamethonium bromide might have its small sing effect in the same way as *d*-tubocurarine. Accord- 1 mg. of neostigmine was given with surprising and diate recovery of respiration.

patient showed no overt signs of myasthenia and d a curare-sensitivity test.

seems that before pentamethonium bromide is at all extensively—especially in "medical" peutics—the possibility of its risk in myasthenics d be further investigated.

don, E.11. J. BARNARD.

VACCINATION UNDER THE N.H.S. ACT

R,—In his report[1] on infant vaccination in England Wales during the six months, July–December, 1948, E. T. Conybeare, of the Ministry of Health, shows in this period, the first half-year under the new Act, proportion of infants vaccinated fell to about half t it was before the Act came into force. He concludes rticle by saying :

> "If the figures for 1949, when they become available, ow that the decline of infant vaccination under the ational Health Service is not temporary, measures, such an increase in the number of vaccination clinics . . . and e working out of some plan to facilitate domiciliary infant ccination in areas not served by such clinics, may be gently required. Such measures, pursued with the energy t into the campaign for immunisation against diphtheria, ight well produce similar results and make the child pulation of this country as well vaccinated as that of the nited States or other countries, where protection against mallpox is regarded as the important matter that it doubtedly is."

s not Dr. Conybeare rather begging a highly debatable stion when he makes that final assertion ? Is a well-cinated child population really so very important in tecting a community against smallpox ? Surely there great deal of valid evidence pointing to the opposite clusion. Decline in infant vaccination is not a new nomenon—it has been going on continuously for r half a century—but, so far from its having been owed by an increase in smallpox mortality, the mor- ty has fallen steadily until now it is practically ligible.

Moreover, in those parts of the country where the line in infant vaccination has been greatest the same rease in smallpox mortality has been witnessed. us, in the city of Leicester the average proportion of ants vaccinated has for very many years been under (Dr. Conybeare tells us that it has now fallen to %), yet during the past 40 years there have been ly two deaths from smallpox, and other places have d a similar experience. After all, it is adults who are st exposed to the danger of smallpox, and the effect infant vaccination in protecting this section of the mmunity is very doubtful. It may reasonably be argued at infant vaccination, by masking the disease in adults, hen the protection conferred on the individual is earing off, neutralises—or more than neutralises—any lue to the community derived from the partial munity conferred on the individual adult.

Incidentally, in the 14 years, 1932–46, there were in ngland and Wales only 28 smallpox deaths (an average 2 per annum in a population of 40,000,000), and not one of those deaths was in an infant under one year of age. Yet in the same period there were 51 deaths from vaccination in infants under one year of age.

Dr. Conybeare mentions admiringly the United States "and other countries." What other countries, including the U.S.A., can show better results in dealing with smallpox than Great Britain ?

So I venture to suggest, with all respect to Dr. Conybeare, that perhaps infant vaccination is not so very important a matter in protecting a community such as ours as he seems to think.

Leicester. C. KILLICK MILLARD.

CONTROL OF TUBERCULOSIS

SIR,—I have read with great interest Dr. Hoffstaedt's letter of Oct. 8. Like him, I admire the efforts of frustrated chest physicians in anticipating the sanatorium-applicants' treatment during their waiting period, but I feel that a word of warning would not be out of place.

We are, many of us, becoming accustomed to admitting patients in whom some form of collapse therapy has been undertaken in the home. The results of such treatment have not, however, been uniformly successful ; often the requisite period of bed rest before the induction of collapse therapy has not been observed, and in many cases we should have preferred to receive the patient with an untouched pleural space.

I cannot subscribe to Dr. Hoffstaedt's statement that some scheme of early ambulatory collapse treatment should be adopted. It is our experience that collapse therapy should not be undertaken lightly—certainly not until after some months of bed rest. After induction, the patient requires careful and prolonged observation and grading if the onset of effusion and other complications is to be avoided. By getting patients into hospital, inducing collapse, and quickly returning them to their home environment, thereby short-circuiting sanatorium treatment, we shall, in my opinion, be courting disaster.

Furthermore, with streptomycin and *p*-aminosalicylic acid now available "over the counter," another possible danger arises in that chest physicians will be greatly tempted to prescribe these drugs during the waiting period, with the result that the sanatorium physician may be further misled as to the patient's natural powers of resistance. In short, I feel that many sanatorium physicians would agree with me that, whenever possible, they would prefer to receive their patients "preconditioned" by bed rest only.

INTERPERSONAL FACTORS IN ILLNESS

SIR,—In his article last week, Dr. Casson referred to the possible benefit of bringing together patients with similar ailments.

Dr. Böhler, in Vienna, made excellent use of this factor. Before the days of plaster-jackets spinal fractures meant long invalidism, and in order to convince patients of the freedom of movement the jacket provided, there were separate wards for spinal cases. New arrivals saw exercises performed and weights lifted a few days after application of the jacket. One man, a taxi-driver, continued his duties while wearing it. The emotional uplift thus provided encouraged even the most fearful to respond. Similar arrangements for other fracture cases worked equally well.

Romford, Essex. H. SYMONDS.

SIR,—The following passage in Dr. Casson's article supports the almost universal fallacy that addiction to tobacco and alcohol are vices :

> "The average doctor . . . may also condemn in his patients what his conscience does not allow in himself, and this moral severity may cloak itself as professional solicitude. For instance, the doctor may forbid alcohol or tobacco . . .

Can turn Fehling's solution from blue into red.

*** Our peripatetic correspondent of Sept. 10 (p. 487) replies: "Blast! I should have asked Mrs. Brown whether her lodger took dextrose, lævulose, mannitose, lactose, galactose, aribinose, pyrocatechin, hydroquinone, or salicylates in his tea."

Letters to the Editor

SEEING THE PATIENT THROUGH

Sir,—Will you allow me to thank your corres
for their letters on this theme? They have done
valuable underlining and suggested new aspects
unlimited topic.

Professor Witts (Sept. 24) hunted in vain for
almoners. He will find them taking part in a
conference half-way down column 4; but I grant
the brevity of the reference may have hidden my
viction of their immense importance in any scheme
hospital coördination. We can be grateful for
description of their highly developed function in his
unit. Mr. Roy Goulding has sought to define a p
for the student in the dealings between patient
hospital; I am certain that the systematic weekly
round he suggests is the right way to keep him
with his patients' progress—in order that he may an
their questions sensibly—and of emphasising the patie
identity as something more than a teaching case.

Two main issues have crystallised out of this co
spondence; first, the internal hospital organis
for seeing the patient through, with which I conce
myself particularly in my paper; secondly, what
may call the hospital-doctor relationship.

I believe that the machinery for seeing the pat
through hospital is usually in existence, although it
often faltering for lack of drive or creaking for lack
lubrication. Miss G. L. John, medical records off
to the Bermondsey and Southwark Hospital Man
ment Committee, a "specialist in coördination," (Sept.
gives an alarmingly comprehensive account of her fu
tions; she slides her tentacles around hospital dep
ments like a well-meaning octopus and I feel that w
her work is finished not only the "absent mind
leave-taking houseman" (who will take this descrip
to heart, no doubt!) but the rest of the medical s
also will be able to go on indefinite furlough. No; t
agencies are already there, under the control of hos
governor or medical superintendent, and I fear that
the long run the coördinator will sap rather th
stimulate their initiative; voluntary and sustai
concentration on the welfare of the patient by each agen
is a much better recipe.

Lastly, the hospital-doctor relationship. To my mi
the most valuable letters in the correspondence have co
from general practitioners; I am particularly indebte
to Dr. Lindsey W. Batten (Oct. 1) and agree with eve
word he writes. This is really the crux, that *it is t*
patient's doctor and not the hospital who must see h
through. With the present hierarchical system
medicine in which the technical rules supreme, the
is a tendency for the hospital to skim the cream off gene
practice and monopolise all that is important
interesting. This process *must* be reversed if gene
practice is not to be impoverished; the hospital m
emulate the best standards of consultant practice
taking infinite pains over the patient and feeding h
back to his doctor with a garnish of helpful informat
and advice.

Taking infinite pains is the only possible form
In the midst of many medical frustrations it is a gui
to the lasting satisfaction of seeing the patient throu

J. M. Lipscomb.

St. George's Hospital, London, W.1.

PENTAMETHONIUM BROMIDE

Sir,—Pentamethonium bromide is at present und
a shadow in the anæsthetic world because of side-effect
which the physician may be able to use.

A substantially fit woman of 47 had a cholecystectom
under anæ [illegible] nitrous oxide and oxy
40%, and [illegible] During $1^3/_4$ hours she h

is motley crowd of registrars has completely upset previous reasonable ratio of those in training to alist and consultant staff. To aggravate the situation is evidence (vide your advertisement columns) that nt policy is still further to increase the establishment gistrars. It is immoral to offer such training to n for whom, at the end of his term, there will not y hope or prospect of advancement. That is what w being done, and the situation is all the more because many of these are men who were registrars e the war and whose careers were interrupted by ce in the Forces. They have been "through the " and have acquired their skills in the school of ical and clinical experience. It was unjust even ntemplate grading such men according to the iples laid down for grading committees when "no nt was to be given to military or previous experi-" and it is unforgiveable to indicate to these men general practice is their future. Are there then y too many specialists? No: any such experienced ar can tell of an increasing volume of specialist fully undertaken by him as the accepted deputy of consultant chief. Why then has establishment of ialists been so niggardly and so dilatory in its rance? Is it economic and financial pressure? direction? Or is it reluctance to spread the privileges pecialist status?

he fact remains that many a *fully trained* man is being sacrificed on the altar of indecision and lost the National Health Service which previously anded specialists. Has the policy changed in "one successful first year"? It has been suggested that would be in the interests of the younger generation training if these *fully trained* men were shelved. ly this must be resisted with all vigour, because it result in a number of disillusioned, embittered, and unded men. Time presses, for many in this dilemma e already been given notice of the termination of r appointment.

or the future, let there be a known establishment registrars, both in the teaching and non-teaching itals, on a regional basis, with senior registrarships rved for those who have the aptitude. Let there be easonable relation between senior registrars and cialist and consultant staff: and let there be frank, sympathetic and considerate, advice to registrars who not up to standard to abandon specialism and to themselves to a career more suited to their ties. Such timely advice will earn the gratitude very reasonable man, no matter how much his pride urt at the time: and ultimately the service will efit, for each man will find his proper place.

SENIOR REGISTRAR.

VASCULAR STASIS

SIR,—Dr. Sevitt tells us in his letter last week that e M.R.C. burns unit has discovered "that the inflam-tory reaction plays an important part in influencing e course of burns." I wonder if they told Metchnikoff? We are also told "that the development of stasis of e local blood-flow in the dermis was preceded by rked œdema, was associated with analgesia, and was lowed by whole-skin loss." This I take to be a scription of blister formation. If so, it does not ite agree with what anyone who has opened a blister ll have noticed—that the pattern of the skin can still e made out at the bottom of the blister and the site of in glands still be seen. Also the blistered area is still inful: only the skin outside the blister is insensitive. f course, "scrubbing" the base of the blister may iterate the skin pattern. The pain diminishes with ister formation but not to the point of analgesia.

In man the preservation of the deeper layers of the kin is part of the rationale for using anti-histamine rugs. If they are exhibited, healing can take place from the base of the blistered area instead of the periphery as would be the case if the whole depth of the skin were lost. (Penicillin must be given as well since most burns are infected early.) A similar phenomenon can be observed in small blisters which are simply protected against bursting and not opened for 7–10 days. At the end of that time their base will be found covered by a fairly thick epithelium. If the whole thickness of skin were separated by blister fluid, healing would take longer and the skin be thinner than it is at the end of 10 days.

I cannot say why Dr. Sevitt has failed to get any effect with anti-histamines in guineapig burns, since he gives no details. But in man they help. Dr. Sevitt's failure to get results is surprising since I can identify at sight a burn that has had 3–4 days' anti-histamine treatment.

Manchester.   S. SHUBSACHS.

ANONYMOUS CRITICISM

SIR,—There has been in the last few days, in the columns of the *Daily Telegraph*, a correspondence devoted to medical matters. Many of your readers will have seen it, so I need only say that someone, signing himself F.R.C.S., has written objecting to the fact that anæsthetists receive the same sessional remuneration as surgeons. This has provoked replies, some signed and some over a nom-de-plume.

I would ask the hospitality of your columns to make a strong plea that if any of us should feel impelled to criticise the relative worth, the activities, or the remuneration of any other branch of the medical profession, then he should do so in a medical journal and not in the lay press. At this time of shifting values, and with the traditional independence of our profession imperilled, it is of supreme importance that we should discuss and settle our domestic differences inside the profession. It is unnecessary to flaunt such matters before the public gaze.

In these columns, Mr. Patey[1] has made a protest against the increasing practice of anonymity. This instance well illustrates the merit of his remarks. Although it may be conceded that anonymity is justifiable if the writer fears reprisals from those he exposes, it certainly does not apply here. Who among us has ever witnessed the economic phenomenon of a surgeon reduced to a state of indigent penury through having incurred the displeasure of his anæsthetist?

Above all, anonymous belittlement of another branch of one's own profession should cause us most concern. Extension of this practice hardly bears contemplation.

London, W.8.   G. C. STEEL, D.A.

LEAD NIPPLE-SHIELDS

SIR,—I should like emphatically to support every word of Mrs. Blacksell's letter last week. In many mothers with cracked nipples attending welfare clinics, we find that it is a choice between weaning the baby and healing the cracks with lead nipple-shields. Only last week I saw a mother who had failed to feed her first 11 babies owing to cracked nipples. Before she was driven to weaning her 12th child for the same reason, the health visitor recommended and loaned lead shields —with, of course, due instructions about washing the breast before letting the baby suck. The cracks were healed in two or three days; the shields were used for about a fortnight: and the baby was breast-fed without further trouble.

We are now to be robbed of this invaluable aid to breast-feeding because harm has resulted from its grossly improper use in one case. It seems scarcely credible. Cannot harm result from the misuse of almost any therapeutic agent?

As Dr. Mackay and Dr. Hunter say in their letter of Oct. 8, lead shields are widely recommended in this to a degree not warranted by the patient's condition, withal in perfect good faith."

---

[1] Patey, D. H. *Lancet*, 1948, ii, 572.

Smoking tobacco and drinking alcohol are not primarily questions of conscience—moral issues. They are questions of infection—"psychological infection," it is true—and primarily medical issues. The drug addictions (including addiction to tobacco and alcohol) are specific diseases, like so many other diseases; they are specific intermittent intoxications, whose seriousness depends on the degree of intoxication—the heaviness of the "smoking" or "drinking" in the present case.

Drug addicts are notoriously untruthful, particularly where their drug is concerned; and addicts of tobacco and alcohol have successfully and almost universally propagated the untruths that tobacco and alcohol are luxuries, and smoking and drinking merely bad habits (vices). Vice or moral deterioration (one of whose manifestations is untruthfulness) is, however, merely a symptom. It is secondary to craving. The disease is drug addiction.

The great majority of our profession are addicted to one or other or both of the drugs, tobacco and alcohol. We, the "watch-dogs" of health, are ourselves drugged, *and it is not surprising therefore that we fail on an immense scale to honour our profession—to eliminate disease.*

Wallasey. LENNOX JOHNSTON.

ACUTE MASTITIS

SIR,—Mr. Walsh's article (Oct. 8) shows the close similarity of this complaint in man and in other species.

Some points which may be of practical importance suggest themselves. Thus in the dairy cow, where the question of mastitis is very important, no-one would nowadays dispute the supremacy of penicillin therapy. The mode of application differs, however, from that in *man. The penicillin is injected directly up the teat* canal, either as an aqueous solution or in oily suspension. I believe that the same method is possible in the pig with a fine-bore needle, but I can testify that in the dog and the cat it is virtually impossible.

In the cow routine systemic penicillin therapy is rather expensive, but intramammary inoculation plus sulphonamide by mouth is commonly practised. Whether systemic penicillin can produce a concentration of the drug in the mammary gland approaching that from direct intramammary inoculation has often been debated; clinical experience suggests that in the cow the latter method is infinitely superior, and it also permits the ready introduction of other drugs when penicillin fails.

The question of harm resulting to the child from suckling at an infected breast is one of interest to a veterinarian. An old-fashioned method of treatment employed by farmers is to put a calf to suckle a cow with mastitis which has not responded to other remedies. This method has much to commend it, for I have never seen harm ensue and on occasion the results have been surprisingly good. The calf evidently suffers no harm and the quarter yields to a more persistent method of stripping than anything man can devise. In the bitch, on the contrary, the milk may be a dangerous source of infection for the puppies when the mother contracts metritis, as she not uncommonly does soon after whelping. For the puppies to contract fatal septicæmia the breasts do not even need to be infected, although they commonly are. This condition is generally ascribed to a hæmolytic streptococcus, and prompt penicillin therapy of both mother and pups is necessary if the latter are to be saved. The bitch, however, generally recovers fairly easily unless multiple abscesses form in the breasts. This syndrome in the bitch can be prevented by either administering a sulphonamide or injecting penicillin immediately after whelping. Similarly in the cow a great deal of mastitis is prevented by prompt penicillin therapy either immediately before or after calving wh any of the exciting factors are present—for examp retention of the placenta, general chills, and bloc teat duct. Again, the other period of great dang when the cow is being dried off and milk stagnati occurs, offers scope for preventive therapy.

In conclusion, the wise farmer nowadays has penicillin ointment always handy for immediate appl tion at the merest suspicion of an abrasion, crack, sore in the region of the teat orifice.

Blackburn. A. H. Hogg.

THE REGISTRAR

SIR,—Before the second world war, those who w registrars were considered to have reached the low rung of the specialist ladder, and they had reasonab hope, if not assurance, of promotion. The duration this period of waiting and completion of training vari but was on the average about five years; these speciali in training, however, embarked on this career fu realising the necessity for forbearance in hardship, making sacrifices, and for sustained application to wor and were generally men imbued with enthusiasm a professional ideals in the best tradition. A constant sp *to their efforts, it is important to emphasise,* was t almost certain prospect of promotion. Why was thi It was because there was a reasonable proportion of tho in training to specialist and consultant staff, and y *there was the healthy competitive element* which i always desirable.

Such a system almost assured the production of th registrar best suited and equipped for specialist stat for it was mainly those who had determination, singlene of purpose, and an indomitable spirit who stayed th course. There was thus a process of "natural selection, and these qualities, combined with the trained min made for the sound judgment, discrimination, an *breadth of vision so eminently* desirable in a speciali Admittedly there were in this system those who, bles with private means, did not suffer hardship; but i must be remembered that they too had the resolve *to train and fit themselves for* greater responsibilities. Even under these favourable circumstances such a apprenticeship made an appeal only to those who fel a call that would not be denied.

Today the scene is entirely changed. The registrar i no longer "the man of promise" and his prestige i rapidly waning owing to the enormous increase in hi number. This increase is the outcome of the appea made to the profession to train more and more specialists for the National Health Service. Whence this appeal emanated it is difficult to ascertain; was it from the Royal Colleges, or was it laid down in the policy of those responsible for launching the service? Whatever its source, it has resulted in an enormous band of postgraduates training in the specialties either as established or as supernumerary registrars (both in teaching and non-teaching hospitals), all striving feverishly in the minimal space of time to attain specialist rank. *It is depressing* and is a matter of grave concern that specialism i indulged in and encouraged before the basic principles of medicine and surgery are even partially acquired. Specialism should be built upon the firm foundation of clinical and practical experience, and this cannot be gained in two or three years as some post-war registrars seem to think. The entrance lists for examinations in the postgraduate diplomas have assumed gigantic proportions, and the oft-repeated attempts of many who were never equipped even to be registrars are eloquent testimony of their ineptitude.

Yet many succeed, and it would appear that the next phase in the struggle is to be recognised as a senior registrar. It is erroneously contended that the holding of a postgraduate diploma automatically calls for recognition as a senior registrar.

Taylor, Shambhoo Datta Tewary, John Watson, G. F. J. Williams.

ANNUAL DINNER

The annual dinner, on Oct. 12, was attended by Princess Elizabeth and by the Duke of Edinburgh, who spoke appreciatively of the college's contribution to the lessened maternal and infant mortality. This, though the youngest of the Royal Colleges, was the first to become a Commonwealth body. He congratulated Prof. Hilda Lloyd on her appointment as its president. Sir William Gilliatt, the retiring president, said that a fund was being launched for the purchase of larger premises; the building now occupied had been opened nearly twenty years ago by the King and Queen, then Duke and Duchess of York. In this age, he continued, it was especially easy to allow standards to fall; and he hoped that the colleges would help to maintain and enhance standards. He ended by pointing out that Professor Lloyd was the first woman to be elected president of a British medical college. In welcoming among the guests Miss Mabel Liddiard, president of the Royal College of Midwives, Mr. J. A. Stallworthy suggested that her task had been complicated by premature Ministerial deliveries, which, he hoped, presaged the third and last stage of labour. In his reply, Sir Bennett Hance referred to the assistance that could be rendered by the college to the Indian subcontinent, dwelling particularly on the needs of Pakistan, where, he said, the doctor-patient ratio is 1 : 8000. The high maternal mortality indicated that only the fringe of the obstetric problem had been touched. Some, with population pressure in mind, regarded this appalling mortality with greater complacency; but population pressure was the concern of the politician and of Providence. Mr. Geoffrey Keynes, who also spoke for the guests, though himself an ex-officio member of the council, refused to identify

country. There must thus be a large number of mothers who have used them, including many who were doing so when so much radio and press publicity was recently given to the matter. What sort of confidence can these women have in the doctor or nurse who advised the use of the shields, now that they have been warned against them in this way?

It seems to me a very sorry state of affairs. The article by Dr. Gordon and Mr. Whitehead, describing the case of lead encephalopathy, is of great interest and importance. But I suggest that it would have been far better if the panic action which preceded and followed its publication had been replaced by the following measures:

1. The circulation of a warning to all general practitioners, maternity departments, and health departments as to the need for care in the instruction of mothers in the proper technique of using lead shields.
2. Arrangement with manufacturers and pharmacists that shields should not be distributed without a leaflet giving similar instructions.
3. The initiation of research to test by experiment the belief of those of us who recommend lead shields that they are completely harmless provided that they are used with proper precautions.

In connexion with this last point, it is to be hoped that any evidence of the value of other methods of treating cracked nipples will be published. Dr. Gordon's statement that "shields made of plastic, or other non-poisonous substances, will be safe and equally effective" is at the moment unsupported by any evidence whatsoever.

Health Department, Oxford. MARY FISHER.

SIR,—In their article of Oct. 8, Dr. Gordon and Mr. Whitehead state finally that "shields made of plastic, or other non-poisonous substances, will be safe and equally effective." A letter by Dr. Mackay and Dr. Hunter in the same issue, commenting on the article, recommends that plastic nipple-shields should be given a trial.

A word of warning seems necessary on the use of the word "plastic" in this rather loose fashion, since the composition of plastic materials varies considerably. Most of them are polymerised chemicals which are comparatively inert and therefore harmless, but they may well contain toxic chemicals which have been added as lubricants, stabilisers, and plasticisers. These may in some instances be extremely toxic—e.g., tri-ortho-cresyl phosphate—and to make matters worse they have been known to "bloom" out of the final plastic. Even lead salts are used as stabilisers in certain well-known plastic materials.

Most plastic materials are, of course, quite harmless; and, what is more, harmless plasticisers can be substituted for those which are toxic. Some manufacturers always recommend that their customers should use only certain plastics for purposes that might otherwise produce ill effects. Those used, for example, to manufacture medical instruments or appliances, containers for food or drink, and the like are carefully selected or made with materials which are believed to be harmless.

There exist, however, so many manufacturers of the final product that the use of plastics containing toxic chemicals for unsuitable purposes cannot be entirely excluded. Plastic articles made from such materials as polymethyl methacrylate or 'Polythene' have already been used for medical purposes, and I suggest therefore that they would at first sight seem suitable for the manufacture of nipple-shields. The use of other plastics for this purpose should be considered only after ensuring that they have no toxic properties.

Notes and News

MIDWIVES IN THE NEW SERVICE

IN its latest annual report[1] the Central Midwives Bo surveys with some anxiety the impact of the National He Service Act on the midwife's training and work—a to discussed in these columns a few weeks ago.[2] As early April, 1948, the board informed the Ministry of Health of apprehensions over the probable effect of instituting a l general-practitioner obstetricians and of offering a special to general practitioners attending their own patients. board fears that these measures may have the effect relegating the midwife to the status of maternity nurse, of reducing recruitment of practising midwives, who hit have been attracted by the opportunities for indepen practice. "These opportunities . . . are the only real ad tages which the midwifery profession has to offer to the irregular hours and the arduous nature of their wo compared with health visiting and other callings requ *similar qualifications.*" *Moreover, if pupil-midwives* are be suitably trained for the second examination, they sho have ample opportunity for conducting normal confinements; and any diminution in the number of do ciliary confinements conducted as midwives' cases can result in either a lowered standard of training or a reduc in the number of midwives trained. But even if a reduc in the number of well-trained midwives is contempl they should still be sufficient to cover the whole country to supply the Colonies, which depend on British midw training. The board reiterates the view expressed by Goodenough Committee that

> "In the conduct of labour the pupil-midwife has more techni experience during her training than the medical student, and would be neither wis [illegible] encourage between midwife and [illegible] the care of nor labour. The conduct c [illegible] is the primary essential obligation of [illegible] unity. The med practitioner has many others which may be both urgent exacting."

The board points to the new [illegible] ding in the W of the improved training propc [illegible] arty Midwives.[3] Last December the shortage [illegible] nate led 14 training schools to apply for concessions to enable th pupils to sit the second examination. The number of dist cases available for training has fallen steadily owing not on to (*a*) the incursion of the general practitioner into nor midwifery, but also to (*b*) a decrease in the birth-rate, witho a relative decrease in institutional confinements, (*c*) economic pressure forcing the mother to choose institution confinement, and (*d*) housing shortage, which often mak domiciliary confinement unsuitable. To carry through th Working Party's proposal, the board would have either increase the domiciliary-training facilities or to decrease th number of approved places. *The Working Party* suggeste that the present division of training should cease, but th board rejects this proposal for the time being, particularly since its adoption would jeopardise the staffing of hospi beds. The board is also reluctant to implement the Work Party's recommendation that, until a new system of trainin is introduced, only State-registered nurses should be train as midwives; several training schools now depend on no State-registered nurse candidates.

During 1948, 17,819 midwives notified their intention to practis The total (which has steadily increased from 15,615 in 1942) 419 greater than that for 1947. Of last year's total, 5679 (31 were non-State-registered nurses. The number of women w notified their intention to act as maternity nurses only was 3 The number of pupil-midwives entering first-period train institutions during the year ended March 31, 1949, was 486 less th in the previous year; and the number of second-period pupils by 199. Of the 4025 pupil-midwives entering first-period at schools in 1948–49, 3777 (94%) did so for the reduced period training allowed to State-registered nurses and registered sick children's nurses.

At March 31 this year, 15,897 midwives and pupil-midwive (9094 of whom were in practice in 1948) had been trained in the administration of nitrous-oxide and air analgesia. In pursuit of a recommendation by the Royal College of Obstetricians and Gynæcologists, the board has asked the Home Secretary to amend the Dangerous Drugs Regulations to

THE DOCTOR'S CREED

AN ADDRESS TO MEDICAL STUDENTS *

GEOFFREY FISHER
P.C., M.A., D.D.
ARCHBISHOP OF CANTERBURY

FOR a fully effective life, a man must have a firm, thful. adequate belief about life. Normally a man y, if he likes, borrow it at second hand from the con- ational doctrine of his generation. Today he cannot : there is no established, conventional, generally epted doctrine of life. Truth is fragmented : each ence cultivates its own plot and is a law to itself and mystery to everyone else. Man is fragmented : the onomic man, the industrial man, and the like. Life is strated : for there is no unity of faith and purpose out it. All of us today are compelled, if we think at , to make a deliberate and intelligent choice. For a an, to choose none is to be a nihilist. Each man, erefore, must work for his belief, and not least the edical profession ; for its members are accepted and usted as guides and advisers in much more than atters of health. They touch men's lives at many nsitive points. If priests in their own craft, they are astors too, and they must have a clear, surely based, ctrine of life behind them.

Against this background—may I venture to raise rtain fundamental questions, closely related to aspects the medical profession ?

THREE QUESTIONS

The pursuit of scientific truth, in which you are rained, is a grand, exciting, exacting, and splendid iscipline indeed. There is the acquisition of exact and recise knowledge by observation, experiment, the nspired guess, even by accident. There is the testing f it by applying it and seeing what trial and error teach ou. And then out of it come fresh problems, fresh tudy, and more truth. That is all magnificent and nthralling. On all this I want to make three obvious bservations, which because they are obvious are the more easily overlooked.

1. Scientific truth is discovered, not created by you. It was there before you found it in the universe, whether it be the truth of nuclear energy or of penicillin. What you do is not to create truth, but to find it and use it. From the beginning of time it was there awaiting your discovery—and not only scientific truth, but the laws of reason and principles of intelligence on which it rests. How did it get there ? If that be a mystery, it is not one that we can ignore. There are three possibilities. It got there by accident, which means that Chaos is King ; it got there by an inherent necessity, which is another way of saying that we do not know ; or it got there by the deliberate act of a Mind which put it there. In which case we recognise an affinity between that mind and ours. It is in Creation—how ? There is *a metaphysical question*.

2. Pure science is concerned only with truth and error. But as soon as you put it to use, it involves you in good and evil, and moral values. Pure science produced the atom bomb. That bomb has shaken Japan and mankind. Even more it has shaken the scientists ; for the thing can be used and its use raises moral questions which men cannot avoid. Science cannot be a law to itself : it demands to be subject to a moral control of its uses. Medical science is constantly and increasingly involved in moral problems. Once it was the simple problem of healing disease. But what of—to give one instance only—what of artificial human insemination—with all the complex questions attached to it of personal and family and social well-being ? It is no longer possible to rest quietly in the simple belief that what science or medical science can do, it may do.

Science, or rather the use made of it, must be subject to the moral judgment ; unless, of course, you like to say there is no such thing as a moral judgment. In which case I reply (*a*) you deny the experience of mankind that there is ; (*b*) you don't believe it yourself ; for there are some things you could not bring yourself to do because they are wrong. But if there is a moral judgment—then, since it is to control life, it deserves study and care as thorough as science itself, and not an unscientific, haphazard, and amateur guess. There is *an ethical question*.

3. Both science and the moral judgment are possessions of Man. Man is greater than the things he possesses, prior in thought to them and superior in essence. What is Man that medical science should serve him ? Unless you have a working answer to that—your work will be in the strict sense of the word faithless and futile. And if it is a mystery, all the more reason for seeking the truth of it.

You see and deal with man as a physical body. But you are never unaware that he is something more. What more ? How much more ? You are all compelled, as any pastor is, to be something of a psychologist. What does a man's ψυχή make him ? In the end an ego, a person, or an *Id*—that thing. And if an ego, a person—how far does that take him (and you, for you too are a man) in terms of moral value and of the purpose of his creation ? There is *a personal problem*.

Well, there are three problems or mysteries. Is creation an accident or a design, and if a design, can we read it ? Is the moral judgment an illusion or in truth a reflection of something in the design and a matter of moment ? Is man a person or a thing—and if a person, confined within the physical order, or reaching beyond it, and if so how far ? Neither a man nor a doctor nor a generation can be at peace and purposeful without some kind of an answer.

I ask—is the medical student trained to find the answer ?

And I answer, almost certainly, no.

Why not ? First because this generation has no settled faith, and a medical school would be hard put to it to know what official answer to give or teach. Secondly, because it is not supposed to be their job.

Nor is it quite. And yet it matters intensely that medical students and their seniors should neither ignore these mysteries nor get hold of false answers nor pick up a ragbag of ideas about them, but should know the best that can be known.

THE CHRISTIAN ANSWERS

I shall now tell them and you, in the fewest possible words, what is the answer of the Christian Faith.

1. *Metaphysical Problem*

Creation—its origin and upholding—is not accident, but design ; and that not unconscious design, but the design of God. God is the creator of all things and holds all things living in life, and therefore is relevant to every problem, metaphysical, moral, and personal.

A priest said to a young man of his flock the other day " I am going to ask you a question : I want you to answer it straight off without stopping to think. Would God be able to understand radar ? " And the young man at once said " No." The Christian Faith says " Of course he does ; it is out of his workshop ; and just as he knows all about radar so he knows all about you." There is a metaphysical unity of truth for you !

---

* Substance of an address delivered in opening the new session of the university medical school at Birmingham on Oct. 4.

this young college with Cinderella; for was not Cinderella always innocent and good and her two sisters elderly and unpleasant? In the end he likened the college to Aphrodite, who is said to have risen from the waves.

Manx Health Services

Dr. T. Lloyd Hughes, Prof. C. A. Wells, Mr. A. A. Gemmell, and Dr. E. Noble Chamberlain are visiting the Isle of Man to advise on the replanning of hospitals and medical services there.

University College Hospital

The dinner of past and present students of the medical school will be held at the Savoy Hotel, Strand, London, W.C.2, on Friday, Oct. 28, at 8 P.M., when Mr. J. B. Hunter will be in the chair. Tickets (*27s. 6d.*) may be had from the dinner secretary, University College Hospital medical school, University Street, W.C.1.

British Medical Students' Association

The annual general meeting of the association will be held in B.M.A. House, Edinburgh, from Nov. 11 to 13. Mr. P. Eggleton, D.SC., will give the guest lecture. Subjects chosen for discussion will include student health services, clinical conferences, staff-student discussions, further education and training grants, and medical films.

Health and Diet in Old Age

Prof. W. Hobson, of the department of social and industrial medicine at Sheffield University, is directing an inquiry among elderly people into the effects on health of dieting and advancing age. The inquiry is being conducted with help from the Nuffield Foundation, the Social Survey, and the Sheffield Council of Social Service.

Mothercraft Exhibition

This exhibition will be held at Central Hall, Westminster, from Nov. 23 to 30. The National Baby Welfare Council have arranged a conference to be held concurrently. Further particulars may be had from the organising secretary, Universal Exhibitions, 40, Holland Park, W.11.

Infant Milk-foods

Proprietary infant milk-foods and National dried milk may now be had as an alternative to liquid milk for children up to 2 years of age. Since April, 1948, supplies of these foods have been restricted to children up to 1 year of age. Anyone wishing to take advantage of this alternative for a child aged 1–2 years should take or send the child's ration book to the local food office.

Messrs. Sharp and Dohme Ltd., Hoddesdon, Herts, inform us that inquiries for 'Tyrozets' should be addressed to them and not (as stated in their advertisement last week) to Messrs. Boileau and Boyd Ltd., Dublin.

Births, Marriages, and Deaths

BIRTHS

BURNS.—On Oct. 12, in London, the wife of Dr. Stewart Burns—a son.

DOHERTY.—On Sept. 29, the wife of Dr. Michael Doherty—a daughter.

FAWCETT.—On Oct. 8, in London, the wife of Dr. J. W. Fawcett—a son.

FISHER.—On Oct. 8, at Luanshya, Northern Rhodesia, the wife of Dr. A. C. Fisher—a son.

FRANKS.—On Oct. 14, in London, the wife of Dr. L. M. Franks—a son.

GILFORD.—On Oct. 12, the wife of Mr. W. W. Gilford, F.R.C.S.—a daughter.

GREGORY.—On Oct. 8, at Aylesbury, the wife of Mr. T. S. S. Gregory, F.R.C.S.—a daughter.

HART.—On Oct. 8, in London, to Dr. Mary (née Sawday), wife of Dr. Robert Hart—a daughter.

HEBBERT.—On Oct. 5, the wife of Dr. John Hebbert—a daughter.

ISAACS.—On Oct. 8, in Manchester, the wife of Dr. H. D. Isaacs—a daughter.

LLOYD.—On Oct. 7, at Swansea, the wife of Dr. Joseph Lloyd—a son.

MARRIAGES

BROOKES—HUGHES-STANTON.—On Oct. 15, in London, Claud James Brookes, F.R.C.S.E., to Barbara Hughes-Stanton.

CARMICHAEL—DALL.—On Oct. 6, in Edinburgh, A. Brian Carmichael, M.B., to Isabel Dall.

DEATHS

JAMES.—On Oct. 13, in London, Richard Gostwycke James, O.B.E., M.R.C.S.

KYLE.—On Oct. 8, in London, James Kyle, M.R.C.S., air commodore, R.A.F. medical branch (rtd).

WATSON.—On Oct. 15, at Bath, Andrew Gordon Watson, M.D. Edin.

Diary of the Week

OCT. 23 TO 29

Monday, 24th

UNIVERSITY OF LONDON
1.45 P.M. (University College, W.C.1.) Dr. Charity Weym Technique and Applications of Tissue Culture (Firs two lectures.)
MEDICAL SOCIETY OF LONDON, 11, Chandos Street, W.1
8.30 P.M. Mr. Terence Cawthorne, Mr. Ian Robin: Deafness.

Tuesday, 25th

ROYAL COLLEGE OF SURGEONS, Lincoln's Inn Fields, W.C.2
5 P.M. Mr. E. S. R. Hughes: Development of the Mam Gland. (Arris and Gale lecture.)
UNIVERSITY OF LONDON
5 P.M. (St. Mary's Hospital Medical School, W.2.) Prof. C. Schmidt (University of Pennsylvania): Physiology *Pharmacology of the Cerebral Circulation.*
INSTITUTE OF DERMATOLOGY, Lisle Street, W.C.2
5 P.M. Dr. I. Muende: Histopathology of the Skin.
INSTITUTE OF OBSTETRICS AND GYNÆCOLOGY
2 P.M. (Postgraduate Medical School of London, Ducane W.12.) Mr. Lawrence Abel: Mammary Cancer in P nancy.
3 P.M. Prof. L. S. P. Davidson: Anæmia in Pregnancy.
EUGENICS SOCIETY
5 P.M. (26, Portland Place, W.1.) Sir Godfrey Thomson, D. Intelligence and Fertility—an Investigation of Scott Children.
EDINBURGH POST-GRADUATE BOARD FOR MEDICINE
5 P.M. (University New Buildings.) Dr. Denis Williams: N Orientations in Epilepsy.

Wednesday, 26th

INSTITUTE OF OBSTETRICS AND GYNÆCOLOGY
11 A.M. (Chelsea Hospital for Women.) Mr. C. S. Gwilli Vaginal Hysterectomy.
NOON. (Prof. E. C. Dodds, F.R.S.: Œstrogens.
ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 23, Portla Place, W.1
3.30 P.M. Dr. H. E. Magee: Popular Fallacies regarding Hum Nutrition.
UNIVERSITY OF GLASGOW
8 P.M. (Department of Ophthalmology.) Dr. A. Wright Thomson Gyrate Atrophy of the Choroid.

Thursday, 27th

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, S.W.1
4.30 P.M. Dr. Desmond Curran: Psychiatry lecture demonstra tion.
INSTITUTE OF UROLOGY
5 P.M. (Royal College of Surgeons, Lincoln's Inn Fields, W.C.2 Mr. A. E. W. McLachlan: Manifestations of Osseo *Syphilis.*
MEDICO-LEGAL SOCIETY
8.15 P.M. (26, Portland Place, W.1.) Dame Louise McIlroy: C of Scientific Research in Medicolegal Practice. (Presidenti address.)
HONYMAN GILLESPIE LECTURE
5 P.M. (Edinburgh University New Buildings.) Dr. Bruce Williamson: Diastole.

Friday, 28th

UNIVERSITY OF LONDON
5.30 P.M. (Westminster Medical School, S.W.1.) Prof. V du Vigneaud (Cornell University): Indispensability o Biologically Labile Methyl Groups in the *Diet* and Trans methylation. (First of three lectures.)
MAIDA VALE HOSPITAL FOR NERVOUS DISEASES, W.9
5 P.M. Dr. S. Nevin: Psychiatry demonstration.
MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, W.1
8 P.M. Colonel L. W. Harrison: Is Treatment before Diagnosis on Suspicion of Venereal Disease advantageous to the Patient and/or the Public Health?
ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh
8 P.M. Sir Philip Manson-Bahr: The Dawn of Tropical Medicine (the Life and Work of Sir Patrick Manson).

Appointments

BARRAN, G. F., B.A., M.D. Camb.: whole-time consultant chest physician, King's Lynn and West Norfolk area.
*STEWART, R. H. M., M.D. Lpool: asst. senior M.O., Manchester Regional Hospital Board.

The Hospital for Sick Children, Great Ormond St., London:
ALCOCK, R. J., M.B. Camb.: house-surgeon.
BACK, E. H., M.B. Camb., M.R.C.P.: house-physician.
D'ARCY, JOAN, M.B. Belf.: resident M.O., Tadworth Court.
MITCHELL, R. G., M.B. Edin., D.C.H.: house-physician.
RENDLE-SHORT, T. J., M.A., M.B. Camb., M.R.C.P., D.C.H.: house-physician.

* Amended notice.

CORRIGENDUM: *Clues to the Ætiology of Graves's Disease*—We regret to find that in publishing Professor Means's lecture on Sept. 24 we introduced another error besides the one corrected last week (*capable* for *incapable* on p. 547). In the 5th and 7th paragraphs under Adrenal Cortex (pp. 547, 548) Professor Means is made to refer to *addisonian anæmia* (i.e., pernicious anæmia) when he was in fact speaking of *Addisonians* (i.e., sufferers from Addison's disease). We trust that the error will have been evident to readers.

THE DOCTOR'S CREED

AN ADDRESS TO MEDICAL STUDENTS *

GEOFFREY FISHER
P.C., M.A., D.D.
ARCHBISHOP OF CANTERBURY

For a fully effective life, a man must have a firm, thful, adequate belief about life. Normally a man y, if he likes, borrow it at second hand from the con- ntional doctrine of his generation. Today he cannot ; there *is* no established, conventional, generally epted doctrine of life. Truth is fragmented : each ence cultivates its own plot and is a law to itself and mystery to everyone else. Man is fragmented : the nomic man, the industrial man, and the like. Life is ustrated : for there is no unity of faith and purpose out it. All of us today are compelled, if we think at , to make a deliberate and intelligent choice. For a an, to choose none is to be a nihilist. Each man, erefore, must work for his belief, and not least the edical profession ; for its members are accepted and usted as guides and advisers in much more than atters of health. They touch men's lives at many nsitive points. If priests in their own craft, they are stors too, and they must have a clear, surely based, octrine of life behind them.

Against this background—may I venture to raise rtain fundamental questions, closely related to aspects the medical profession ?

THREE QUESTIONS

The pursuit of scientific truth, in which you are ained, is a grand, exciting, exacting, and splendid iscipline indeed. There is the acquisition of exact and recise knowledge by observation, experiment, the spired guess, even by accident. There is the testing f it by applying it and seeing what trial and error teach ou. And then out of it come fresh problems, fresh tudy, and more truth. That is all magnificent and nthralling. On all this I want to make three obvious bservations, which because they are obvious are the nore easily overlooked.

1. Scientific truth is discovered, not created by you. t was there before you found it in the universe, whether t be the truth of nuclear energy or of penicillin. What ou do is not to create truth, but to find it and use it. rom the beginning of time it was there awaiting your iscovery—and not only scientific truth, but the laws f reason and principles of intelligence on which it rests. ow did it get there ? If that be a mystery, it is not ne that we can ignore. There are three possibilities. t got there by accident, which means that Chaos is ing ; it got there by an inherent necessity, which is nother way of saying that we do not know ; or it got here by the deliberate act of a Mind which put it there, n which case we recognise an affinity between that nind and ours. It is in Creation—how ? There is *a* *question.*

ience is concerned only with truth and error. ut as soon as you put it to use, it involves you in good nd evil, and moral values. Pure science produced the tom bomb. That bomb has shaken Japan and mankind. Even more it has shaken the scientists ; for the thing can be used and its use raises moral questions which men cannot avoid. Science cannot be a law to itself : it demands to be subject to a moral control of its uses. Medical science is constantly and increasingly involved n moral problems. Once it was the simple problem of healing disease. But what of—to give one instance only—what of artificial human insemination—with all the complex questions attached to it of personal and family and social well-being ? It is no longer possible to rest quietly in the simple belief that what science or medical science can do, it may do.

Science, or rather the use made of it, must be subject to the moral judgment ; unless, of course, you like to say there is no such thing as a moral judgment. In which case I reply (*a*) you deny the experience of mankind that there is ; (*b*) you don't believe it yourself ; for there are some things you could not bring yourself to do because they are wrong. But if there is a moral judgment—then, since it is to control life, it deserves study and care as thorough as science itself, and not an unscientific, haphazard, and amateur guess. There is *an ethical question.*

3. Both science and the moral judgment are possessions of Man. Man is greater than the things he possesses, prior in thought to them and superior in essence. What is Man that medical science should serve him ? Unless you have a working answer to that—your work will be in the strict sense of the word faithless and futile. And if it is a mystery, all the more reason for seeking the truth of it.

You see and deal with man as a physical body. But you are never unaware that he is something more. What more ? How much more ? You are all compelled, as any pastor is, to be something of a psychologist. What does a man's ψυχή make him ? In the end an ego, a person, or an *Id*—that thing. And if an ego, a person—how far does that take him (and you, for you too are a man) in terms of moral value and of the purpose of his creation ? There is *a personal problem.*

Well, there are three problems or mysteries. Is creation an accident or a design, and if a design, can we read it ? Is the moral judgment an illusion or in truth a reflection of something in the design and a matter of moment ? Is man a person or a thing—and if a person, confined within the physical order, or reaching beyond it, and if so how far ? Neither a man nor a doctor nor a generation can be at peace and purposeful without some kind of an answer.

I ask—is the medical student trained to find the answer ?

And I answer, almost certainly, no.

Why not ? First because this generation has no settled faith, and a medical school would be hard put to it to know what official answer to give or teach. Secondly, because it is not supposed to be their job.

Nor is it quite. And yet it matters intensely that medical students and their seniors should neither ignore these mysteries nor get hold of false answers nor pick up a ragbag of ideas about them, but should know the best that can be known.

THE CHRISTIAN ANSWERS

I shall now tell them and you, in the fewest possible words, what is the answer of the Christian Faith.

1. Metaphysical Problem

Creation—its origin and upholding—is not accident, but design ; and that not unconscious design, but the design of God. God is the creator of all things and holds all things living in life, and therefore is relevant to every problem, metaphysical, moral, and personal.

A priest said to a young man of his flock the other day " I am going to ask you a question : I want you to answer it straight off without stopping to think. Would God be able to understand radar ? " And the young man at once said " No." The Christian Faith says " Of course he does ; it is out of his workshop ; and just as he knows all about radar so he knows all about you." There is a metaphysical unity of truth for you !

---

* Substance of an address delivered in opening the new session of the university medical school at Birmingham on Oct. 4.

2. Ethical Problem

The moral judgment deals with realities (partially known as all realities are) because it *derives from God.* The Good really is good because it corresponds with the being of God, and Evil really is evil *because it conflicts* with the Perfection of God—*and thank God for that.* It really would be ghastly if at the heart of *everything* there really was no difference between the two, or even if Evil was God—*the ultimate sovereign.*

And the Christian Faith then does two things *more for* us: first it trains us to judge moral questions, our own and other people's, *not by our own ideas but by what* God has revealed of His *Ideas*; and like any good *educationalist, God does not say "There's the answer at the end of the book," but "Here are the principles. Work it out for yourselves and I will help you."*

Secondly, the conflict of good and evil is real to God and to us. The process of overcoming evil with good is unceasing. Every man helps or hinders. Moral judgment is not an intellectual exercise but a personal *commitment to a share in the battle.*

3. Man

What is Man? The Christian Faith says, on our side, from our end, Man is a being who "has *the capacity to* hear *the* word of God and respond to it," and, from God's side, Man is the object of God's love, as God has shown in His own acts. *Hence flow all the doctrines of the Christian Faith.* So we *believe in the Incarnation.* So we can believe in a personal *commitment of God through the Incarnation, physical defeat, and Bodily* Resurrection. He did what we can believe, but could never believe *had he not done it. And* Man's part is to hear what God has done and respond to it. *That is all* I can say without making this more *of a sermon than* it is already.

So far has my consideration of the scientific aspect of medicine brought me. I have said *these things to* medical students, because they touch their profession closely. Many medical students don't often hear them and still less *often think of them. Yet* as a hypothesis, they have as much to be said for them as any medical hypothesis, and no-one has a right to look askance at them, *until he is quite certain that he has a better* hypothesis which will better equip him for his life and for his work.

SOCIAL AND PERSONAL ASPECTS OF MEDICINE

In what is left of my time may I hurriedly refer to two other aspects of medical work.

1. The Social Aspect

Here the Church and the medical profession ought to have sympathy for one another, for both of us now are "established," in a measure. You draw part of your salaries from the State; we draw not a penny piece from the State. But you and we have a State connexion. We are intimately involved in the Welfare State and work for its welfare, and—and this is the point I want to make—we both insist that that State connexion shall leave us absolutely free to deliver the truth that is in us—to care for persons, and for their true health, by our own highest standards.

And why? We are here to serve our people. We have and recognise our obligation to society. We intensely believe in the Welfare State, in the sense of a State which serves the true welfare (as we may see it) of all its people and does all to help it. Yet we *look* beyond and above the State for our principles. They are sacred. You have your medical creeds, and there is the Christian creed. They are sacred and cohere because they are both of God and not of man.

2. The Personal Aspect

When all is said and done—about scientific approach and social service—the end of science and of *society is Man in himself and in his social relations.* That is the whole point of the struggle against totalitarianism. Man and the family have their indefeasible rights and dignity which may not be overridden or denied, because they are not the result of sociology or State law, but are of God *and to be respected by Man. And your job* and mine is *to serve Man* in his own person and in his family, relieving *his distresses of body* and soul, preserving him in health *of body, mind,* and soul because he is not an *Id*, or an *average, or a bit of statistics,* but a fellow creature bound to us and we to him as members one of another *in the family* of God whose nature is Love. Body and soul are closely allied. The parson has his job with the souls of *men* but *again* and again he can't do it without help of the doctor. The doctor has his job with the bodies of men, but again and again he cannot do it without the *help of a priest.* That is being rediscovered. We cover the same ground and belong to one another, as from the beginning of the Christian era we always have. The blessed doctor is the general practitioner *He sees and knows not a case,* but a person; not a person sole, but a person in his family. He is the family doctor. Nothing in State service must destroy that. Consultant specialists are a degree more remote (like bishops!): and therefore (again like bishops) they need a double dose of Grace to keep them sensitive to the personal and *pastoral.*

THE DOCTOR'S CREED

And this last word: if doctor and priest are covering the same ground with their complementary prescriptions, the doctor needs to be anchored to a Faith as good and compelling, true and exacting, as that of a priest. For he has to *deliver the goods—spiritual* as well as physical He must have a creed that impels him to value, care for, respect each *man, and if he is to* have that, it must be a creed which governs *him himself.* For I believe that what *men look for* and need and pray for in a doctor is something over and above his skill in medicine. It is *a sure touch—in the things* of the *spirit.* And as I have said, no man has the right to reject or by-pass the Christian Faith unless and until by prayer and fasting he *has convinced himself* of a Faith truer, better, and which exacts more and not less from him.

TOPECTOMY

THE TREATMENT OF MENTAL ILLNESS BY FRONTAL GYRECTOMY OR BILATERAL SUBTOTAL ABLATION OF FRONTAL CORTEX[*]

J. LAWRENCE POOL
M.D., D.Med.Sci. Columbia
PROFESSOR OF NEUROLOGICAL SURGERY
From the Service of Neurological Surgery, The Neurological Institute of New York

TOPECTOMY (from τόπος, a place, region, or part, and ἐκτομή, a cutting out) is an operation used for treating mental illness (Pool et al. 1949). It can equally well be described as frontal gyrectomy (Penfield 1947) or bilateral subtotal ablation of frontal cortex (Heath and Pool 1948).

Burckhardt in 1890 reported encouraging results of limited unilateral ablation of temporal and frontal cortex in a few psychotic patients. Later Moniz (1936) introduced bilateral frontal leucotomy, which was subsequently modified by Freeman and Watts (1942), Scarff and Kalinowsky (1947), Poppen (1948), and others. In the laboratory Fulton and Jacobsen (1935) were among those who demonstrated the effects on behaviour of bilateral ablation of frontal cortex, and Mettler in

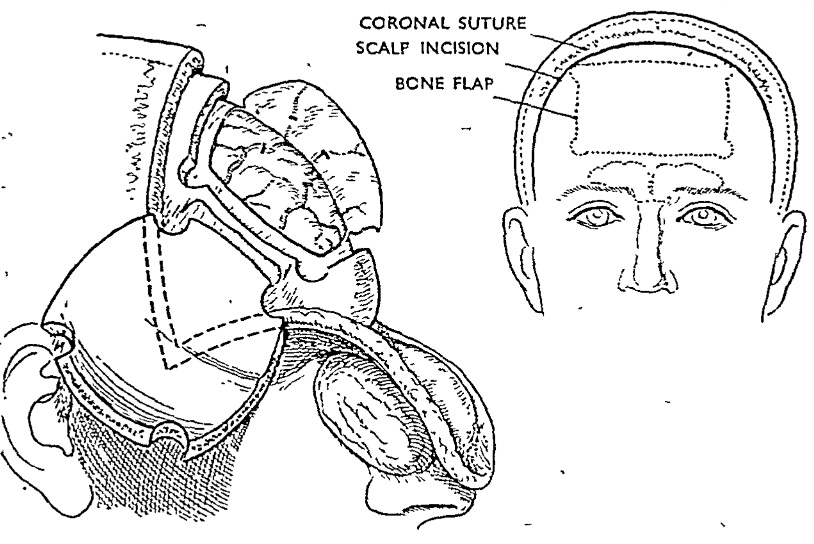

Fig. 1—Scalp incision, bone flap, and dural opening for topectomy.

44 suggested that behaviour changes in laboratory imals were associated particularly with bilateral moval of Brodmann's area 9. For this reason, in our iginal topectomy operations an effort was made to cise at least a portion of what we believed to be rodmann's area 9 (Heath and Pool 1948). My associates, r. Robert G. Heath and Dr. John Weber, and I felt hat such an operation could safely be done.

Our reasons for doing topectomies instead of lobotomies ere as follows:

(1) We hoped that relatively small cortical ablations ould prove more specific as regards the site and extent of he lesion and might therefore yield equally good therapeutic esults without as much cerebral dysfunction.

(2) We hoped that by purposely varying the site and xtent of cortical excisions valuable information might be btained about the rôle of various portions of the frontal obes in mental illness.

(3) We expected that special studies during these operations ould shed light on still other facets of frontal-lobe functions.

How far these hopes were realised will, I hope, be revealed below.

The first topectomy was performed in 1946 (Heath and Pool 1948), and early in 1947 an elaborate study of various types of topectomy or bilateral frontal gyrectomy was conducted (Columbia-Greystone Associates 1949). In my opinion this preliminary work indicated that the best therapeutic results were obtained in those patients from whom cortex was removed bilaterally in the region of Brodmann's areas 9 and 10. Accordingly the topectomy operation as subsequently done by me has been largely confined to symmetrical excision of cortex from the rostromedial portion of each frontal lobe, presumably representing parts of Brodmann's areas 9 and 10.

Later Penfield (1947) described, without enthusiasm, the results of a somewhat similar operation called frontal gyrectomy. However, his experience seemed to parallel ours to the extent that he also noted adverse personality changes when the surgical lesions extended too far posteriorly—i.e., caudal to the plane of the coronal suture. Moreover, in one case of Penfield's showing significant postoperative improvement the cortical ablation was quite similar to that currently used in topectomies.

SELECTION OF PATIENTS FOR TOPECTOMY

The first 52 patients on whom topectomy was done have all been observed for more than a year, and some for nearly three years. Though most of them were private patients, little effort was made in this initial series to select cases according to the severity of their illness or to their prognosis. In general, essentially the same criteria were used in selecting cases for topectomy as for lobotomy (Scarff and Kalinowsky 1947, Poppen 1948), the operation being reserved with few exceptions for those cases in which psychotherapy, shock therapy, and sometimes psycho-analysis, had failed.

In the light of our total experience with this operation it now seems clear that topectomy is less radical than the so-called standard prefrontal lobotomy (Freeman and Watts 1942) as regards the amount of frontal lobe sacrificed, and more radical than transorbital lobotomy (Freeman 1948). This is an impression that may serve as a further guide in the selection of patients for topectomy.

PREOPERATIVE AND POSTOPERATIVE STUDIES

Before operation all patients were subjected to a physical, neurological, and psychiatric examination, a complete blood-count, blood-Wassermann test or its equivalent, analysis of urine, and sometimes other special studies. Electro-encephalography, radiography of the skull, and psychometric studies were also done whenever possible. After operation an effort was made to repeat these tests.

ANÆSTHESIA

Anæsthesia consisted of intravenous thiopentone sodium, supplemented by nitrous oxide/oxygen by inhalation through an intratracheal tube, and local infiltration of the scalp with 1% procaine solution.

OPERATION

All operations were carried out in one stage. A coronal type of scalp flap was reflected anteriorly, and a single bone flap hinged on the right temporal muscle was turned, crossing the midline so that both frontal lobes could be exposed. The posterior edge of the bone flap was cut close to or just anterior to the coronal suture, the anterior edge being cut as far forward as the frontal air sinuses permitted (fig. 1). Laterally each flap extended 4–4·5 cm. from the midline. Though four burr-holes were usually sufficient, in cases with an unusually thin or adherent dura additional burr-holes were made in the midline posteriorly and anteriorly so that the dura could be separated from the bone without undue tearing. After bleeding from the dura had been controlled with the electrocautery, a dural flap was opened over each frontal lobe. The superior cerebral veins were next divided between silver clips or by cauterisation so that the cortex could be exposed medially on each side along the falx cerebri (fig. 1).

Resection of Cortex

A block of cortex was excised symmetrically from each frontal lobe, beginning about 2 cm. anterior to the junction of the coronal and sagittal sutures and extending laterally for 3·0 to 3·5 cm., anteriorly 5·5–6·0 cm., and in depth 1·9–2·0 cm.—i.e., to the depths of the grey matter but no deeper (fig. 2). The site and extent of resections were also checked with reference to readily recognisable landmarks, such as the tip of the frontal pole, the sylvian, frontal, and precentral fissures, the falx, and the sphenoid ridge. In some cases the motor cortex was electrically stimulated also. Resection was greatly facilitated by first occluding the major arterial channels supplying the designated block of cortex, by placing silver clips on the appropriate branches of the anterior cerebral arteries medially, near the inferior margin of the falx. The cortex was then removed easily either by a subpial suction technique or simply by incising to a depth of 1·9 cm. with a scalpel blade at right angles to the surface of the cortex. Further hæmostasis was accomplished with silver clips or the electrocautery, both methods having been used, usually in combination. In earlier cases the cortex was resected chiefly with interrupted black silk ligatures passed through the cortex on curved needles, but this technique was soon discontinued.

It was sometimes necessary or advisable to complete the removal by slightly undercutting the margins of the excision with gentle suction, especially anteriorly if large frontal sinuses prevented adequate exposure. After the cortical incision had been made, a slightly curved spatula was employed to undercut the block of cortex and thus complete its removal. The edges of the cavity were next made smooth and even with a small-calibre suction tip. Each block of cortex thus removed should weigh about 25–30 g. in the fresh state. In a psychotic patient anything less than this amount usually proved therapeutically ineffective. However, Le Beau et al. (1948), who have used this type of operation to relieve intractable pain, feel that in the non-psychotic patient removal of only 15–20 g. from each side is sufficient, and that more than this may induce permanent undesirable personality changes. In a word, the quantity of cortex removed seems a most important factor.

Closure

In every case the cerebral cavities caused by the operation were lined with a thin layer of 'Hemopak' (an oxidised cellulose prepared by Johnson & Johnson Ltd.) and filled with 5 ml. of a dilute solution of penicillin 1000 units per ml. The dural flaps were next closed in watertight fashion, and the bone flap replaced and anchored with periosteal sutures. The defects created by the anterior burr-holes were usually closed with tantalum discs (fig. 3). In some cases the opening and closing of the scalp incision was facilitated by the use of ordinary 'Zipp' fasteners instead of sutures—a technique developed by the author. A snug head dressing was then applied, well reinforced in cases where postoperative violence might be expected.

POSTOPERATIVE COURSE

The usual postoperative course of the topectomy patient differed considerably from that of the patient who had undergone a standard prefrontal lobotomy. The topectomy patient tended to be less depressed and disoriented, especially during the first 24 hours after operation, and most of them recognised their friends and family, read the papers, and ate during the 1st postoperative day; while some even walked about, and did picture puzzles. From the 2nd to the 5th postoperative day, and sometimes longer, the post-topectomy patients often showed an exacerbation of their preoperative psychotic symptoms. This tended gradually or sometimes abruptly to subside, with the result that the patient could be discharged by the 10th–14th day. Generally a convalescent period with psychotherapy in a nursing-home was advised for 4–8 weeks before returning the patient to his home. Significant improvement, when it occurred, was usually manifest by the 3rd postoperative month, though some further improvement often took place during the following 3–4 months.

PATHOLOGY

Though in many cases the exposed cortex appeared grossly abnormal, showing atrophy, unusual firmness, or apparent abnormalities of the vascular pattern, there was no obvious correlation between the gross or microscopic appearance of the cortex and the type of psychosis, its duration, or the amount of shock treatment administered (Pool et al. 1949). It did seem, however, that the dura was often exceptionally vascular in most patients who had recently undergone extensive shock treatment.

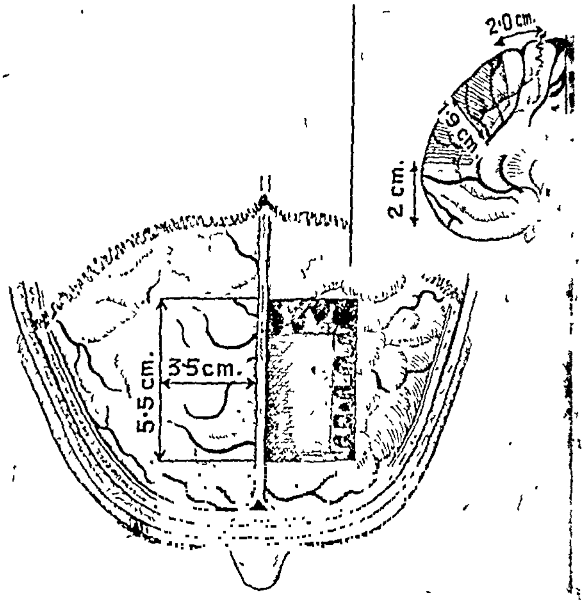

Fig. 2—Amount of cortex ordinarily removed. Somewhat more than this should be removed in chronic schizophrenics, and considerably less for relief of pain.

COMPLICATIONS

Postoperative hæmorrhage occurred in 2 cases, and was successfully treated by prompt re-elevation of the operative flap and evacuation of the hæmatomata. Temporary incontinence of urine occurred in about a third of our patients and lasted for an average of 10 days. In no instance was the incontinence permanent. Retention of urine occurred in 5 cases and likewise was not permanent.

MORTALITY

In this series of private and ward patients, and in another consecutive series making a total of more than 125 topectomies so far done by me, there has not been a single death from the operation.

ELECTRO-ENCEPHALOGRAPHY AND CONVULSIONS

In these patients there were no significant preoperative abnormal appearances in the electro-encephalogram (E.E.G.). For 10–28 days after operation most, but all, patients had focal E.E.G. disturbances in the and sometimes adjacent regions, and a few for than this. In most cases the E.E.G. was within limits by the 4th postoperative month. However, those who subsequently had generalised convulsions, a few presented no abnormality in their postoperative E.E.G. pattern before the onset of the convulsions. Of these 52 patients 7 had two or more attacks of postoperative convulsions. Two others may have had one attack each, but the reports on these two cases did not specify this. Thus the known incidence of convulsions was about 14% and possibly nearly 18%. This is higher than the incidence of convulsions after lobotomy, which in some series is reported to be about 10–12%. Fits generally occurred for the first time 4–6 months after operation, with sudden loss of consciousness followed by tonic-clonic contractions, without any aura or focal

In our cases, however, attacks were controlled odium phenytoin and phenobarbitone, provided the were faithfully taken. All the patients who had lsions had a dynamic type of personality: there no convulsions in patients of the "flat" or hebetic type. There seemed to be no correlation between iagnosis, prognosis, or age of the patient and the of fits. Their incidence was slightly higher among arly cases in which the cortex had been ablated silk ligatures, but 2 patients in whom the subpial ique was used (without sutures) also had convul- Excessive use of the electrocautery, however, ed a definite predisposing factor.

the cases developing fits the lesions bordered closely he cingulate gyri (area 24) and presumably on 8 if not 8s, which may be significant in view of ie Russell's interesting hypothesis that post-natic convulsions seem to occur most often in the nce of injury involving supposed suppressor zones e cerebral cortex (Russell 1947).

CORTEX AND E.E.G. AT SECOND OPERATION

7 cases of this series a second operation was done months after an initial topectomy which failed, for urpose of removing more cortex from areas 9 and 10. ach case the dura was found to be lightly adherent e cortex for 1–2 cm. all round the previous excision. nearly 1 cm. round the scar the presenting surface he cortex looked slightly yellow. The site of the ious excision was marked by a rather shallow ession with a smooth glistening lining. Electrical rdings were made with special bipolar electrodes 5 cm. apart, connected to a three-channel inking amplifier. The operations were done under pentone sodium and nitrous-oxide-oxygen anæsthesia. ler these conditions no abnormalities in the electrical vity of the cortex could be detected when electrodes e placed at various points within 1·5 cm. of the edge the cortical scar or at distances up to 4·5 cm. from scar.

n resecting more cortex and subjacent white matter, e increased resistance was noted on cutting tissue hin 1 cm. of the previous scar, but the underlying ite matter seemed macroscopically normal in all but case. In this case microscopy showed a moderate use astrocytosis for a distance of 1 cm.

CEREBRAL CIRCULATION

In some cases the distribution of some of the frontal nches of the anterior cerebral arteries was tested. ore cortical ablation, by injecting the vessels with a r drops of sterile solution of methylene-blue. By this ans it was possible to demonstrate clearly that a rtial overlap of the circulation existed between adjacent anches of the anterior cerebral arteries, and between them and some of the neighbouring tributaries of the middle cerebral artery, illustrating how collateral circulation in the cerebral cortex may take place.

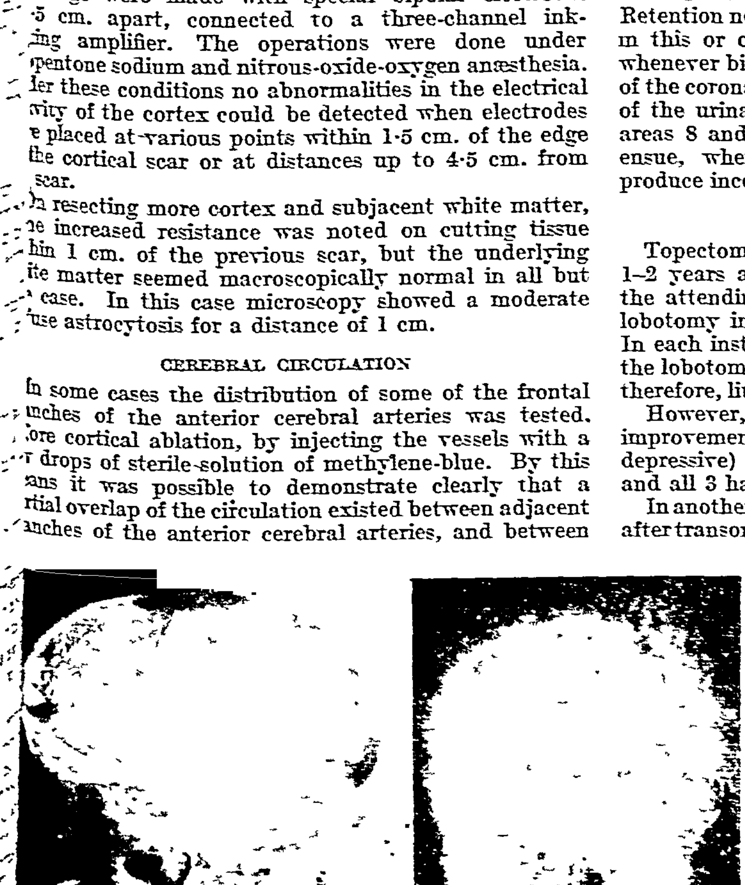

Fig 3—X-ray photographs showing silver clips marking site of ablation of cortex, and tantalum discs inserted into anterior burr-holes for cosmetic reasons.

In 7 cases not included here, frontal and prefrontal branches of the anterior cerebral arteries were clipped with silver clips bilaterally, in the hope of inducing ischæmic changes in that part of the frontal cortex usually excised during topectomy. In 5 patients with an intractable reactive or involutional depression so treated improvement followed operation, though no cortex had been either incised or excised. None of them had convulsions, though all showed temporary E.E.G. changes for 3–4 months in both prefrontal leads. Though this seems a promising and simple operation it is not recommended, because of the possibility that a collateral circulation will develop.

In another small series of psychotic cases, at the request of a group of psychiatrists, the operation was confined to ligation of the superior cerebral or cortico-dural veins over each frontal lobe. This produced no psychiatric improvement but was followed by a relatively high incidence of convulsions, and hence is decried. It is mentioned here to indicate that venous ligation of this kind may be a factor in the production of postoperative convulsions in some topectomy cases.

DYSFUNCTION OF URINARY BLADDER

Of the 52 cases in the topectomy series 5 early ones developed transitory postoperative urinary retention requiring one or more catheterisations. In each of these cases the cortical ablation had extended into what was believed to be the caudal portion of Brodmann's area 9. Retention never followed more anteriorly placed ablations in this or other series, while incontinence was the rule whenever bilateral ablations extended caudal to the plane of the coronal suture. This suggests a dual cortical control of the urinary bladder such that, when cortex close to areas 8 and 6 of Brodmann is removed, retention may ensue, whereas more caudal cortical lesions usually produce incontinence.

TOPECTOMY AFTER LOBOTOMY

Topectomy has been done in 3 schizophrenic cases, 1–2 years after prefrontal lobotomy, at the request of the attending psychiatrists on the supposition that the lobotomy incision might not have been properly made. In each instance, however, it was seen at operation that the lobotomy had been well done. As might be expected, therefore, little improvement followed a second operation.

However, topectomy has been followed by considerable improvement in 3 patients (2 schizophrenic and 1 manic-depressive) in whom transorbital lobotomies had failed, and all 3 have been discharged to their homes.

In another 3 patients who had not improved significantly after transorbital lobotomy a modified topectomy was tried, to see what rôle corticocortical connexions might play. In these 3 cases no tissue was removed. Instead, an incision was made 2 cm. deep in each frontal lobe all round the area of cortex that would have been excised by topectomy. Thus far relatively little change has taken place, which confirms the theory that cortico-subcortical rather than intercortical connexions must be severed in frontal operations to secure clinical improvement.

In some cases in which part of the cingulate gyri or the frontal poles were also deliberately removed there seemed to be little difference in the postoperative behaviour from that in cases in which these regions had not been ablated. This is another reason why the standard topectomy (as currently practised by me)

has been limited to removal of the rostromedial portions of what is believed to represent Brodmann's areas 9 and 10.

In 2 schizophrenic patients in whom lobotomy had failed, slight improvement followed unilateral incision of the anterior thalamic nucleus, and in 2 others some temporary improvement followed bilateral surgical incision of the dorsomedial nuclei of the thalamus.

AUTONOMIC EFFECTS

After Cortical Ablation

During the investigation (Columbia-Greystone Associates 1949), in which various parts of the frontal lobes were excised, pronounced temporary autonomic effects were observed after bilateral subtotal removal of the cingulate gyri (area 24 and part of area 32) and in 2 other cases after bilateral excision of area 44.

Ablation of the cingulate gyri led to several bouts of violent retching, with two episodes of fæcal vomiting. The extremities, which were cold, wet, and clammy before operation, were warm, dry, and pink during the first 2–3 postoperative weeks, but there were no significant alterations of blood-pressure, pulse, or respiration.

Bilateral removal of cortex of the inferior frontal gyri immediately anterior to the foot of the precentral sulci in 2 other cases was followed by temporary emesis and diarrhœa in one, and retching and profuse salivation in the other. In these 2 cases motor aphasia did not follow the bilateral removal of area 44 (presumably representing a part at least of Broca's area), but dysarthria and some facial weakness were observed in one of the cases. These findings are in keeping with the views expressed by Moutier (1908) and others that motor aphasia need not follow lesions involving the so-called area of Broca but is associated rather with deeper lesions.

Associated with Stimulation

In 15 cases in which a standard topectomy was done the rostral cingulate cortex (area 24) was stimulated electrically, and in 1 case mechanically. Significant alterations of blood-pressure and of the cardiac and respiratory rates were observed singly or in combination in every one of these cases, as described by Pool Ransohoff (1940). These autonomic effects are to those reported by Smith (1945), Ward (1948), (1947), and others on stimulation of the rostral cing cortex in animals, and confirm for the first time the that the rostral cingulate cortex in man is analog in function to that of other species.

RESULTS OF TOPECTOMY

In the 52 cases of topectomy involving areas 9 of Brodmann all postoperative results were by my psychiatric colleagues and not by me. A of 4 represents the best results from all points of 3 represents significant improvement, 2 only improvement, and so on, as indicated in the acc table. It is apparent from this table that sig improvement followed in 44% of the topectomies

In the case of the patients who gave the best resu their families, and the patients themselves often st that their emotional and intellectual capacity is the sa as it was before the onset of their illness. One man, w had been unable to work for eight years, was rece kept at his job as a skilled electrician, though seve others in the shop were discharged because busine had slackened. Another, a Government tax expert, ha been promoted since his topectomy. One woman ha been paid handsomely for a magazine article she wro after her topectomy; another has been retained as secretary despite two attacks of convulsions; and Musical and artistic skills are preserved, and busines have returned to their usual office work. One fami wrote that, since topectomy, their mother had becom "100% perfect, with interest in and love for her famil the capacity to act as hostess at dinners, &c., where she had never spoken a single word to her family fo ten years." Some patients, however (but not all even though clinically improved, tend to show distracti bility and fatigability after operation, especially th schizophrenics.

Psychometric studies a year or more after topectomy have shown an improved intelligence quotient, less rigidity of ideas, and evidence of greater social adaptations compared with the preoperative condition.

When improvement took place it almost always became manifest within three months after topectomy. Of those patients who showed significant improvement only 2 have relapsed during the follow-up period of from one to nearly three years.

In 7 of the 52 patients additional cortex from the rostromedial portion of each frontal lobe (area 10) was removed at a second operation, because the first operation, presumably too conservative, had not been beneficial. Of these 7, 4 who were schizophrenic did not improve after their second, more extensive, operation. However a second operation on 1 schizophrenic, 1 obsessive-compulsive, and 1 depressed patient produced considerable improvement. In general, it seems that, if the schizophrenic patient does not improve after a standard topectomy, removal of more cortex, or even lobotomy, will seldom help appreciably.

DISCUSSION

Compared with frontal lobotomy, topectomy takes longer to perform (two or three hours) and leads to a higher incidence of postoperative convulsions. However, there have been no deaths due to topectomy in 125 consecutive cases done by me. Topectomy apparently causes less dysfunction of the frontal lobes than does the usual lobotomy and is perhaps more precise as regards the location and estimated extent of the surgical lesion.

Another advantage, according to our impression, is that after topectomy the emotional and intellectual capacity is apt to be better preserved than after lobotomy, hat, with 2 possible exceptions, none of our patients to have been made worse by topectomy.

ny topectomy, or any type of psychosurgery, is ive, we do not know. However, several points l out. First, it seems to be well established that ition on the prefrontal portion of the frontal lobes sential. Whether there is an optimum zone for cal removal or disconnexion within the prefrontal remains to be shown.

e quant ty of cortex removed seems to be as important ie site of its removal. As a general rule, less cortex be excised in non-schizophrenic patients than in ophrenics, just as still less need be removed in non-hotic patients—e.g., for the relief of pain. In many nically deteriorated schizophrenics it seems that, natter how extensive the operation, no improvement es.

nally, it looks as though we may have to direct operation in some categories of psychotic pat ents abcortical (rather than frontal) structures, such as hypothalamus and the anterior or dorsomedial ei of the thalamus, as Spiegel et al. (1947) have l.

SUMMARY

he operation of topectomy (frontal gyrectomy or otal bilateral ablation of frontal cortex) is described.

he indications for topectomy are essentially the e as for prefrontal lobotomy. The selection of cases be influenced to some extent by the fact that ectomy seems to be less radical than prefrontal otomy but more radical than transorbital lobotomy.

he disadvantages of topectomy are the relatively i incidence of postoperative convulsions (14% in this es) as compared with 10–12% after frontal lobotomy; the fact that the operation takes longer.

he advantages of topectomy are a mortality-rate 125 cases) of zero; better localisation of the lesion a better estimation of its extent; less risk of serious toperative personality changes; and a better oppor-ity for studying the functions of the frontal lobes.

utonomic effects following cortical ablations and gulate stimulation are mentioned, and effects on the ulation are described.

Both the site of the cortical ablation and, more ecially, its quantity are important factors in deter-ning the success of topectomy.

About 44% of all topectomy patients have maintained nificant improvement for periods of from one to nearly ee years after operation.

SELF-ADMINISTERED ANALGESIA IN LABOUR

WITH SPECIAL REFERENCE TO TRICHLORETHYLENE

E. H. Seward *
M.A., B.M. Oxfd, D.A., D.Obst.R.C.O.G.
RESEARCH ASSISTANT, NUFFIELD DEPARTMENT OF ANÆSTHETICS, UNIVERSITY OF OXFORD

There are many ways of relieving the pain of labour. A common practice in this country is to combine general medication with intermittent inhalation analgesia. With general medication, the interests of mother and baby are mutually antagonistic. Pain relief is obtained at the expense of respiratory depression of the infant. Intermittent inhalation analgesia is particularly useful in the few hours immediately preceding delivery; the mother is free of drug action between uterine contractions (which occupy only about a quarter of the time), and moreover the inhaled gases are not likely to interfere with the establishment of the baby's respiration. Another advantage is that the gas mixture may be self-administered and so provide the mother with something to do at a time when her passive rôle in the first stage of labour is becoming difficult to play. The importance of this factor is demonstrated from time to time, when a mother attests to complete relief from pain though unwittingly using apparatus which by error delivers air only.

Yet another advantage of inhalation analgesia, as compared with local or regional analgesia for instance, is that it can be supervised by the midwives, and is suitable for almost any case. Nevertheless there are disadvantages: use of a face-mask often leads to uncomfortable dryness of the mouth, probably due to mouth-breathing; intermittent analgesia does not relieve the continuous backache which is sometimes worse than the pain of contraction; and self-administered analgesia becomes a burden to the mother if it is the sole means of pain relief in prolonged labour.

MANAGEMENT OF SELF-ADMINISTERED ANALGESIA

The early stages of labour can be made comfortable with analgesic and sedative drugs. The place of intermittent inhalation analgesia is towards the end of labour, during a period which includes the most painful phases—namely, the end of the first stage and actual delivery. Correct administration is essential if relief is to be effective, and may be attained by instruction in the use of apparatus before labour begins and careful supervision when it is in progress. The mother's confidence will be lost unless she understands what is going on in labour. She must appreciate the fact that, though pain is relieved, awareness of visceral sensations such as pressure will be retained. As for the gas mixture to be inhaled, there is merit in a mixture of constant composition from an apparatus which needs no adjustment. This applies even in institutions where medical assistance is always to hand, for it eliminates the need for constant medical supervision. Though in theory the anæsthetic requirement of patients is variable, in practice a constant mixture carefully chosen gives very good results. If pain relief is not adequate the mixture can be reinforced by a very small dose of analgesic drug. A 50% nitrous-oxide air mixture is widely used, but in spite of careful administration, even this concentration does not always give the measure of relief desired. Depressing drugs have then to be used in at least moderate dosage and the gas loses much of its safety value with regard to the baby.

A careful study has been made of anæsthetic mixtures suitable for intermittent self-administration. The requirements are (1) a rapid onset of effect, (2) a rapid elimination of the gas between inhalations, and (3) the possibility of continued use for 4–5 minutes (at delivery) without taking the average patient into the stage of uninhibited reaction or full anæsthesia. There is usually about 15 seconds' interval between the beginning of a uterine contraction and the development of pain from it; so analgesia should be obtained within 15 seconds, which allows 6 comfortable deep breaths. The apparatus should deliver a mixture which remains constant irrespective of the patient's breathing, for the respiratory activity of women in labour varies greatly both in rate and depth, the variation being an expression both of the emotional state of the woman and of the intensity of the pain stimulus.

COMPARISON OF ANALGESIC MIXTURES

In the present investigation, a comparison of three anæsthetic mixtures by one observer has been made by close observation of their use in labour. The mixtures were the 50% nitrous-oxide/air—permitted by the Central Midwives Board; a 75% nitrous-oxide/25%-oxygen mixture; and a 0·5% trichlorethylene/air mixture. These percentages are expressed as volume/volume, and the strengths mentioned were adopted in consequence of previous trials. The gas-air apparatus used was either the 'Jecta' or the new Minnitt. The gas-oxygen apparatus was that designed by Andreas Warming of Copenhagen, experience with which has already been reported elsewhere (Royal Society of Medicine 1949). In this intermittent-flow apparatus, nitrous oxide cannot be inhaled if the oxygen supply fails. The trichlorethylene/air apparatus was an experimental one in which compensation is made for changes in temperature. With the last two apparatuse , changes in respiratory minute volume cause negligible changes in the composition of the mixture.

A planned investigation on 150 cases was made of the efficiency of these three mixtures, comparing two in any one labour. Each subject for the investigation received two in successive trial periods of about half-hour each near the end of the first stage of labour, when contractions were strong and regular. On account of the variable factors involved, two series of cases were observed for each pair of mixtures, one mixture being given first in one series and the other mixture first in the control series. Each subject was asked, after a fair trial of each mixture, which was more effective in relieving the pain of uterine contraction. The results were:

		Better		Equal
Nitrous-oxide/air ..	Nitrous-oxide/oxygen	0	49	1
Nitrous-oxide/air ..	Trichlorethylene/air	0	45	5
Nitrous-oxide/oxygen	Trichlorethylene/air	14	12	24

It is clear that nitrous-oxide/oxygen and trichlorethylene/air are both better than nitrous-oxide/air, and that nitrous-oxide/oxygen and trichlorethylene/air are about equally effective.

This trial was followed by observation of a comparable series of labours in which nitrous-oxide/air and trichlorethylene/air were used. Cases were selected at random, the criterion for inclusion in the series being a reasonable prospect of normal labour. Management was uniform in that there was no antenatal instruction in analgesia but careful instruction when administration was commenced. Almost all patients received some other drug as well as the inhaled mixture; these drugs were given in the early stages of labour, followed by inhalation analgesia beginning at half to three-quarters dilatation of the cervix, and further doses were given in the case of inadequate pain relief or requiring sedation. A concurrent series in nitrous-oxide/oxygen was used is not comparabl it was given mainly for abnormal labour. T observations were made:

—	Number of cases	Parity		Analgesia						Other drugs			Compl of labou
				Adequate			Inadequate						
		Primiparæ	Multiparæ	Primiparæ	Multiparæ	Total	Primiparæ	Multiparæ	Total	C	P	H	P.P.H.
Nitrous-oxide/air	100	81	19	32	10	42	49	9	58	80	73	5	5
Trichlorethylene/air	100	75	25	68	23	91	7	2	9	50	47	7	3

P.P.H. = post-partum hæmorrhage of 20 oz. blood or more.

Asphyxia = failure to establish regular efficient respiration 2 minutes of delivery or 30 seconds of clamping the cord.

Analgesia was judged as adequate if visceral sensations experienced without pain.

Other drugs: total number of doses given in whole series.
C = tinct. opii min. 15 and chloral hydrate gr. 30;
P = pethidine 100 mg.;
H = heroin gr. 1/6 or morphine gr. 1/4, with or wit barbiturate.

While the nitrous-oxide/air and trichlorethylene series are comparable as regards complications of labo the trichlorethylene series contains a larger numbe multiparæ than does the nitrous-oxide/air series. T slight balance in favour of trichlorethylene does vitiate the clear-cut difference between the two se as regards effectiveness of analgesia.

Analgesia was estimated in all cases by observati during labour, by questioning within half an hour delivery of the baby and again within twenty-four ho of delivery. (It soon became apparent that questioni only some hours after delivery would give a wrong favourable impression of the analgesia, in that memo of the unpleasant side tends to be dulled very quick though there may be clear recollection of events such moving from room to room and other incidents.) Reli of pain was more effective in the trichlorethylene ser and it was obtained with the use of fewer other drug The series quoted here is too small to justify the conclusi that 0·5% trichlorethylene/air used as routine wou provide adequate analgesia in 90% of all cases.

EXPERIENCE WITH TRICHLORETHYLENE

Trichlorethylene is a potent analgesic agent but the are limitations to its usefulness in labour. These are interest at the present time when attention is being give to the question whether trichlorethylene is suitab for the domiciliary midwife working without medic supervision.

The effect of inhaled trichlorethylene vapour i cumulative, so that if it is inhaled over a long period o time the patient becomes increasingly drowsy. This drowsiness is related to slow elimination of the drug. Using 0·5% trichlorethylene/air mixture, in average labour, drowsiness does not become marked until it has been used for about six hours. This applies when the vapour is inhaled only during contractions. When trichlorethylene is used in this way for longer than six hours, the patient usually becomes drowsy and her coöperation is impaired. When administration is likely to exceed six hours, or where supervision is not close gh to prevent inhalation between contractions. a concentration (0·3–0·4% in air) has been found able. This lower concentration is quite adequate ven in conjunction with pethidine or morphine. when the mother is drowsy there does not appear any falling-off in uterine activity such as to render tive delivery or post-partum hæmorrhage likely count of the trichlorethylene.

ere is a smaller tendency to emotional upset with lorethylene than with the nitrous-oxide/oxygen are, though pain relief is about the same with each. was well shown in the preliminary period of finding cost suitable strength for the mixtures. When the us-oxide/oxygen mixture was too strong many nts became excited by the stimulus of uterine actions and had to be restrained, whereas, when the lorethylene/air mixture was too strong the patient e increasingly drowsy without preliminary excite-. This is in keeping with the greater analgesic r of trichlorethylene compared with nitrous oxide, h reduces the patient almost to the state known in thetic parlance as that of "uninhibited reaction" re comparable pain relief is obtained. For the same n. trichlorethylene is more useful for episiotomy. ive to twenty breaths of 0·5% trichlorethylene/air allow episiotomy to be performed without pain and minor reaction to the physical sensation of cutting, reas with nitrous-oxide/oxygen the reaction may be ssive.

xperience suggests that the 0·5% trichlorethylene/air ture is best suited to normal labour or to a fast-ing labour, where the administration is not expected ast more than six hours. This strength of tri-rethylene has proved helpful for the woman who is tionally tense with only a thin veneer of voluntary trol of her behaviour: here, nitrous oxide will produce obstreperous patient whereas trichlorethylene will w voluntary control to be maintained though pain is ved.

s regards toxic effects, maternal arrhythmia has been rved only once in more than 150 cases. In this case re was bradycardia, the pulse-rate falling from to 48 per minute while trichlorethylene was used, rising again as it was excreted. This patient was he acute stage of mumps at the time of her labour: appeared none the worse for her bradycardia and the hlorethylene was not withdrawn. The fœtal heart- in this case remained steady. Fœtal bradycardia been mentioned by one observer as likely to follow hlorethylene analgesia combined with pethidine yal College of Obstetricians and Gynæcologists 9), but this relationship has not been confirmed.

fœtal bradycardia appears to be a manifestation of gen-lack rather than drug depression. The relation ween inhalation analgesia and fœtal bradycardia has n studied and will form the subject of another article. clinical grounds there is little doubt that trichlor-ylene passes the human placental barrier and that rdosage of the mother often leads to a sleepy baby. initiation of respiration is, usually, delayed only en overdosage with trichlorethylene is combined with other analgesic drug which depresses respiration. this drug is pethidine, the dose should be much reduced half or quarter) from that required in conjunction th nitrous-oxide/air analgesia.

The chief conclusion reached from this investigation that trichlorethylene/air analgesia is at least as cient as other available methods and is particularly itable for certain cases. It is administered from paratus which is easily portable. These attributes trichlorethylene/air analgesia commend it as convenient d safe for domiciliary midwifery. It has also proved useful in a hospital unit handling normal and abnormal midwifery.

SUMMARY

The advantages and disadvantages of self-administered analgesia in labour are considered.

Trichlorethylene 0·5% in air is more effective than the usual nitrous-oxide/air mixture in relieving the pain of uterine contraction.

Nitrous-oxide/oxygen (75–25% mixture) is more effective than the usual nitrous-oxide/air mixture in relieving the pain of uterine contraction.

Trichlorethylene/air is better than nitrous-oxide/oxygen for a fast-moving labour and for the nervous patient, but is not suitable for prolonged administration.

I would like to acknowledge with thanks the facilities afforded by the Nuffield Department of Obstetrics and Gynæcology, and the Area Department of Obstetrics and Gynæcology, Oxford. The work was made considerably easier by the helpful coöperation of the labour-ward sisters and nursing staff of the two departments. I am also indebted to Mr. D. J. Finney, lecturer in design and analysis of scientific experiment, University of Oxford, for his valuable assistance.

SYNTHETIC ŒSTROGENS IN MAMMARY CANCER

A. L. WALPOLE
Ph.D. Lond.
OF THE BIOLOGICAL LABORATORIES, IMPERIAL CHEMICAL INDUSTRIES LTD., WILMSLOW, CHESHIRE

EDITH PATERSON
M.B. Edin., F.R.C.P.E.
MEMBER OF THE RESEARCH STAFF, CHRISTIE HOSPITAL AND HOLT RADIUM INSTITUTE, MANCHESTER

RESULTS already published (Haddow et al. 1944, Nathanson 1946) indicate that the administration of certain synthetic œstrogens to patients with advanced mammary cancer may have temporary beneficial results. In a small proportion of cases there is dramatic improvement, including actual regression of the primary tumour and secondaries; in others the effect is not so striking but some hold-up of the disease results; while in the remainder the disease pursues its course apparently unaffected by the treatment. In all where improvement occurs it is only temporary, and ultimately the disease again becomes active and progressive.

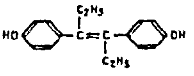
Various factors have been cited as contributing to the wide variation in response to treatment, but the reasons for it are still obscure. Their elucidation might well provide the *rationale* for more effective chemotherapy in this disease.

The mode of action of œstrogens on human mammary cancer is itself uncertain; it is not even clearly established that they act on such tumours by virtue of their œstrogenic activity per se. In the hope of obtaining further evidence on this point the clinical response in a series of patients under treatment with œstrogens has been compared on a quantitative basis with the concomitant changes in the vaginal epithelium—the keratinisation of the superficial cells of the vaginal mucosa being a well-recognised criterion of the response in animals and man to œstrogenic stimulation. Three œstrogenic compounds were used, two of these at more than one dose-level. The opportunity was taken to examine the influence of such factors as drug, dosage, and the age of the patient on clinical and vaginal responses.

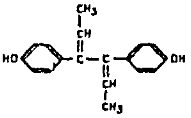
MATERIAL AND METHODS

Œstrogens Used

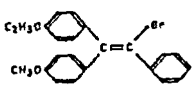
Stilbœstrol, dienœstrol, and 'M.2613' were used. Their formulæ are:



Stilbœstrol



Dienœstrol



M.2613

The two former were used at two dose-levels—high and low. The high dose was 20 mg. per day in four doses each of 5 mg. The low dose was 1·2 mg. per day divided similarly. M.2613 was given at doses of 300 or 600 mg. daily in three doses.

Separate analyses were made of the effects of stilbœstrol and dienœstrol at high and low doses. All cases treated with M.2613 were regarded as one group irrespective of the dose-level.

Clinical Material

In all, 50 patients with advanced carcinoma of the breast were studied. They were selected only in the sense of living close enough to the hospital for ease in follow-up, and of being postmenopausal to facilitate getting smears which would be uncomplicated with the cyclical menstrual changes in the vaginal mucosa. Most of them had had no previous treatment by surgery or X rays and were untreatable by either method when *first seen*. In 18 carcinoma had recurred after amputation, in 5 after X-ray therapy, and in 1 after both. In all the irradiated cases the disease had recurred, generally widely and it is therefore improbable that any response following chemotherapy was due to their previous X-ray treatment. Only 1 patient had had treatment with œstrogens; none had had androgens. The diagnosis was histologically proved in half the cases, but in none of them was there any doubt about the diagnosis, which was clinically evident from the metastases and the subsequent course of the disease.

Assessment of Clinical Status and Progress

Before treatment with œstrogens a detailed examination of the patients was made to ascertain the extent of the disease. Where the primary breast tumour was present its size was measured with callipers and the extent of ulceration was charted. Similar measurements were made of secondary nodules and lymph-nodes. Lung and bone lesions were followed with radiographs. The clinical assessment of the cases before and during œstrogen treatment was made on the measurements of as many of these manifestations as were present—i.e., the size of the primary tumour, the number, size, and extent of chest nodules, and the presence and size of enlarged nodes, and of pulmonary and bone metastases. *In 41 of the 50 patients two or more of these* manifestations were present.

The patients were mainly studied as outpatients. At each visit the amount of drug actually taken was checked as far as possible, a vaginal smear was taken, and the sizes of the lesions were noted. A numerical assessment of the progress of the disease was made at intervals of three months from the start of œstrogen treatment. A score of 0 was given if a manifestation was advancing, of 1 if it was stationary, and of 2 if it was regressing, as compared with its appearance at the start of treatment. The total score for each patient, divided by the number of manifestations exhibited, gave a mean value which in each case was multiplied by 6 to give a whole number, the mean clinical value (M.C.V.). Thus a patient showing regression of the primary lesion and of lung metastases but in whom secondary skin nodules were ad would be given a rating of $\frac{2+2+0}{3}\times 6=8$. The ance of a new lesion—e.g., in bone—was advancing.

TABLE I—REGRESSION-RATE ACCORDING TO SITE OF M FESTATIONS OF MAMMARY CANCER AFTER SIX TREATMENT WITH ŒSTROGENS

Site	Cases	Regressions
Primary	23	10
Lung	7	2
Bone	4	1
Lymph-node ..	26	5
Chest nodules ..	11	1

The Vaginal Smear

One or more preliminary vaginal smears wer before treatment began, and thereafter smea made at intervals usually of one month. The secretion was obtained from the posterior fornix glass pipette as suggested by Papanicolaou (193 from this a thin smear was made on a glass slid was *immediately placed in a* glass specime (3×1¹/₄ in. diam.) closed with a tightly fitting bung. In this way the drying of the smears was r and their staining properties preserved. As possible after being made, the smears were fixed ethanol and stained by a slight modification of the of Shorr (1940).

The cell types commonly found in human smears are described by Papanicolaou (1933) Papanicolaou and Shorr (1936). A quantitative tion of the response was made on the basis of the proportions of the various cell types which appe the smear. Numerical indices were assigned various stages in the transition from a typical menopausal smear showing no evidence of œst stimulation (index=0) to a "fully cornified" (index=9). The method was similar to that u Robson (1938) for the quantitative evaluation of re to œstrogens in the vagina of spayed mice.

RESULTS

Effects on Tumour

The response to the three œstrogens was A quantitative difference dependent on dose was for stilbœstrol and dienœstrol where two widely di

TABLE II—CASES TREATED WITH DIENŒSTROL

3·2	3	2·9 (5)	2	4
1 0 (1)	6	2·9 (4)	6	6
5·8 (2)	12	—	8	21
5 7	6	—	—	16

Another possibility explored was that elderly ents might tend to have lesions which would be rated tationary, so increasing the M.C.V. This was not so. proportion of stationary lesions was the same in the age-groups, while on the other hand the proportion gressing lesions was significantly higher in the over- ies. Thus there is a real basis for the clinical ression that œstrogens are more effective in older ients.

has been thought that breast cancer in some sites respond to œstrogen treatment more favourably n it does in other sites. The regression-rate for the ious manifestations observed after six months' treat- nt is shown in table I. It will be seen that though re were differences in responsiveness they were not striking.

ore interesting was the observation that certain of patients who responded did so in respect of several nifestations. We therefore examined the possibility t in certain patients it was the disease as a whole t responded. The data show that this was the case ; our series the probability on a random basis that a tient would show more than one regressing lesion was ceedingly small ($p=0{\cdot}001$). This generalised type of ponse is one of the factors which must be remembered considering the growth-inhibiting action of œstrogens.

ffects on Vaginal Smear

In tables II, III, and IV the cases are grouped according the drug with which they were treated and the dose- vel employed. In most cases the mean of the first ree and of the first six consecutive monthly smear dices, starting one month from the commencement of treatment, are shown. These are designated M.S.I. (3 months) and M.S.I. (6 months) respectively. When less than the full numbers of consecutive monthly smear indices were available for calculation of the means the actual number used is indicated in parentheses. Together with these are shown figures for the clinical rating of the disease at three and six months respectively from the start of chemotherapy. These are designated M.C.V. (3 months) and M.C.V. (6 months) respectively. Some patients died or were lost sight of before the end of six months' œstrogen treatment ; this is indicated in the tables by a dash. The number of months during which drug treatment was continued in each case is also shown. Where the period was just under three months this is indicated by 2+. No differences were found between the three drugs in respect of œstrogenic effect and no correlation was found between the level of dosing and the response in the vaginal epithelium. The average M.S.I. of patients having the higher doses was almost identical with that of low-dose patients, for both three and six months of treatment. This suggests that the effect on the epithelium can be achieved with the smallest doses, and that where this effect is slight, despite the dose, other inhibitory factors must be operative.

TABLE IV—CASES TREATED WITH M.2613

Case	Three months		Six months		Months on drug
	M.S.I.	M.C.V.	M.S.I.	M.C.V.

48	2·7	0	—	—	3
49	4·5	4	4·4	4	6
50*	5·3	0	4·5	0	7

* No drug for a year before M.2613. Had previously had urethane and before that stilbœstrol and triphenylchlorethylene.

However, a positive correlation exists between age and vaginal response. The average M.S.I. for patients over sixty was 5·18 for the first three, and 5·25 for the first six months of treatment, while the corresponding figures for younger patients were 4·51 and 4·38.

A correlation was sought between the response as shown by the vaginal smears and the clinical response of the tumour. In figs. 1, 2, and 3 mean smear indices of individual patients have been plotted against the corresponding values for clinical response, both on arbitrary scales. It is evident that there is a limited direct correlation between the two. The practical conclusion emerges that patients who show a high M.S.I. may or may not respond to the treatment, while those who fail to show a vaginal response (M.S.I. less than about 4) rarely display significant clinical improvement.

DISCUSSION

The mechanism of action of œstrogens in human mammary cancer is obscure. No satisfactory explanation in terms of the known actions of œstrogens on the normal mammary gland in man or animals has been advanced, and none appears possible yet. It is not even clear that œstrogens act on such tumours by virtue of their œstrogenic activity per se ; but there are several reasons for thinking that they do. For example, their therapeutic effects in cancer are limited to tumours associated with the reproductive system (prostate and breast). In other forms of malignant disease in which they have been tried they have little or no effect (Haddow et al. 1944). There is thus no evidence for regarding them as general inhibitors of tumour growth comparable with X rays.

In the present work we have found three synthetic œstrogens, each a distinct chemical entity, producing effects in mammary cancer which are indistinguishable qualitatively, or even quantitatively (when dose-levels are given in ratio to the effective œstrogenic dose). This is further evidence that the effects on the tumour are but a manifestation of œstrogenic activity. It would be of interest to know the effect of other œstrogens, including those which occur naturally; but as far as we know this has not been studied.

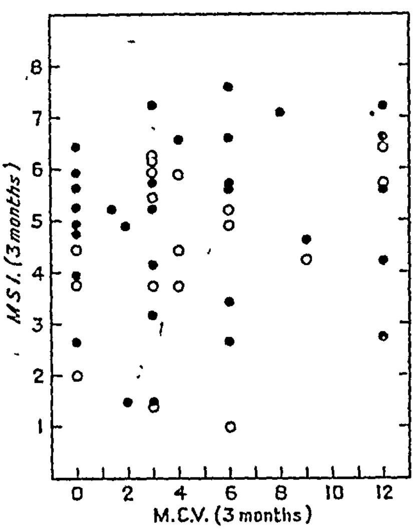

Fig. 1—Mean smear indices (3 months) plotted against mean clinical values (3 months) on arbitrary scales. Each point represents an individual patient. Solid points refer to patients for whom the full number of consecutive monthly smear indices was available for computing the mean, circles to those for whom a smaller number was available.

The fact most urgently requiring explanation is that some patients are quite refractory to œstrogen treatment, whereas in others the disease tends to regress in all its manifestations. Probably many factors contribute to the wide variation in response. The histological grading may be important, as suggested by Lowenhaupt and Steinbach (1949); this aspect of the problem has not been explored by us. We have found, in our patients, some measure of direct correlation between clinical response and vaginal response. This suggests that, where both are poor, some factor or group of factors is involved which tends to prevent both effects. In this connexion dosage and those other factors (absorption, distribution, metabolism, and excretion) which govern the access of the drugs to their site of action, must first be considered. Throughout the present investigation the œstrogens used have been given by mouth; clearly they must be absorbed and pass into the blood-stream in an active form before they can exert their effect on the tumour or the vaginal epithelium. It has been shown that those patients having stilbœstrol and dienœstrol at the higher dose-level showed more clinical improvement than the low-dose patients. Thus with regard to clinical effect such factors as are mentioned above are operative. We have no evidence that in our work the upper dose limits were reached, above which further increase would lead to no further improvement in response. therefore plan to administer these drugs in still doses, and also by the intramuscular route, in the of improving the therapeutic effect. We expect, over, that a limit will be set by an increase in incidence and severity of vaginal hæmorrhage.

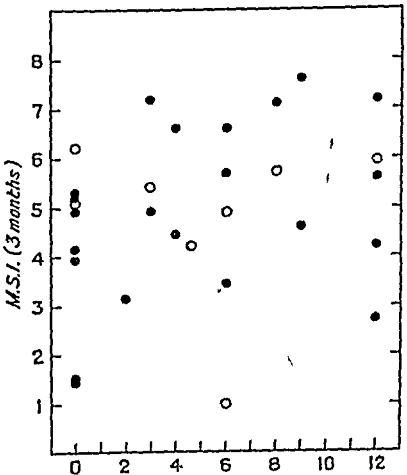

Fig. 2—Mean smear indices (3 months) plotted against mean clinical values (6 months). Conventions as in fig. 1.

The reaction of the vaginal epithelium, on the hand, is not correlated with dosage over the dose which we have employed. It appears that the full achieved with the smallest doses used, and that where effect is small, despite the dose, other inhibitory must be operative. We suggest that such correlation as exists between clinical and vaginal response is referable to such factors, and further, since both responses are correlated with the age of the patients, that those factors are associated with age. We hope to obtain a clearer indication of the existence of such factors from investigations at present in progress.

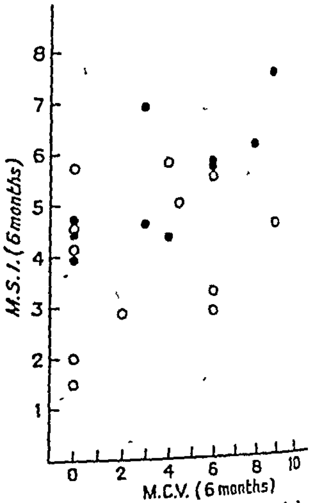

Fig. 3—Mean smear indices (6 months) against mean clinical values (6 m Conventions as in fig. 1.

A noteworthy feature of the results presented ab the almost complete absence of vaginal respon certain patients receiving high doses of œstrogen such patients we are now giving stilbœstrol b intravaginal route. As has been shown by Em (1941) stilbœstrol is a "true" œstrogen in the that it acts directly upon the vaginal mucosa wi having to undergo any preliminary metabolic cha the body. If, with intravaginal stilbœstrol, patients still fail to show any vaginal response we have clear evidence for the existence of inhibitory f quite unrelated to dosage, transport, and metab On the nature of these factors we can only spec It may be that in many of the patients treate vaginal and mammary tissues are inherently insen to œstrogens; it may be that the inhibition is d anti-hormones elaborated by the body, or perhaps malignant cells, which counteract their action. gesterone or androgens, in sufficient concentration, have this neutralising effect.

SUMMARY

The response of advanced mammary cancer to œst treatment has been studied in 50 postmenopausal w and compared on a quantitative basis with the and compared on a quantitative basis with the Concomitant changes in the vaginal epithelium. C improvement was greatest in the older patients a those receiving the higher doses of œstrogen. V keratinisation also was more pronounced in the patients but was not correlated with dosage.

The implications of these findings are discussed.

ERIPHERAL SKIN TEMPERATURE IN NORMAL PREGNANCY

CATHERINE C. BURT
M.B., B.Sc. Edin.
ARCH ASSISTANT, MEDICAL RESEARCH COUNCIL ENDO-
NOLOGY UNIT, UNIVERSITY OF EDINBURGH; CLINICAL
ASSISTANT, THE ROYAL INFIRMARY, EDINBURGH

1948, in the course of studies of peripheral blood- in women in the later weeks of pregnancy, it was nd that the skin temperature of the fingers was ntained at a level higher than that to be expected the environmental temperature (18–22°C); of 20 ients between twenty and forty weeks pregnant 1 had a resting finger temperature of under 30°C. imilar state of peripheral vasodilatation was found 17 of the 20 during the period one to eight weeks r delivery (Burt 1949).

ork on basal temperature changes during the men- al cycle and pregnancy has been published, but little ut circulation in the extremities at those times. ervations on the size and length of capillaries in gnancy have been reported (Hinselmann and Haupt 4, Melbard 1938), and in an investigation of peripheral od-flow during gestation and the puerperium Abramson al. (1943) found that in most women the blood-flow ained within normal limits in the leg and forearm ing the last two trimesters, but that in the hand re was a tendency towards an increase, which persisted some time after delivery. Their observations were ade at a room temperature of 25°C, the water in e plethysmograph being at 32°C.

Particularly in summer, a subjective feeling of warmth ring pregnancy is reported by many patients. In 62 Raynaud recorded that one of his patients invariably agnosed her own pregnancy by her freedom from sospastic attacks, and there is a clinical impression at remissions from vasospastic attacks, chilblains, d acrocyanosis often occur during pregnancy.

I thought that it might be of interest to compare the sting digital temperatures in upper and lower limbs non-pregnant women with those at all stages of rmal pregnancy, at a low environmental temperature.

METHOD

Readings were made of the resting skin temperature the nail bases of all digits of one hand, and digits ne, three, and five of one foot, on 30 non-pregnant olunteers and on 100 patients during either normal regnancy or the puerperium. A thermocouple with a oveable applicator was used (Barcroft). Records ere made in the morning, after a light breakfast, and he room temperature was maintained at 17 ± 1°C. Each woman was rested quietly in bed for thirty minutes with one hand and one foot exposed, and thereafter igital skin temperature, pulse-rate, and blood-pressure were recorded at five-minute intervals for a further period of thirty minutes. In some cases records were obtained at several stages of pregnancy, and 16 patients were followed throughout pregnancy at intervals of about four weeks.

Observations were begun in September and continued until April; hence during the greater part of the time outdoor temperature tended to decrease. In addition, to obviate error from possible acclimatisation to winter conditions, during each month, except in the small group followed throughout pregnancy, readings were made at many stages of pregnancy.

RESULTS

Average Digital Temperature after Exposure to Room Temperature of 17°C for One Hour.—Average finger and toe temperatures at the end of the thirty-minute period were calculated in the non-pregnant controls. at four-weekly intervals during pregnancy, and during the first two weeks of the puerperium (fig. 1). In the controls average finger temperature was 22·3 ± 0·72°C (S.E. mean). During pregnancy it showed a gradual rise from 22·5 ± 1·02°C at five to eight weeks (a level nearly the same as that of the controls) to 34·2 ± 0 13°C during the last four weeks. All the patients examined during the last four weeks maintained full vasodilatation in the hands during the period of exposure. A small reduction to 33·3 ± 1·3°C was found in patients examined during the first two weeks of the puerperium. In the controls the average toe temperature was 19·9 ± 0·25°C (S.E. mean). During pregnancy it was 21·2 ± 1·1°C from the fifth to the eighth week, and did not show significant change until the twenty-fourth to twenty-eighth week, when it rose to 25·0°C. During the last four weeks the average toe temperature was 26·0 ± 1·2°C, and in the puerperium 23·0 ± 0·94°C. In fingers and

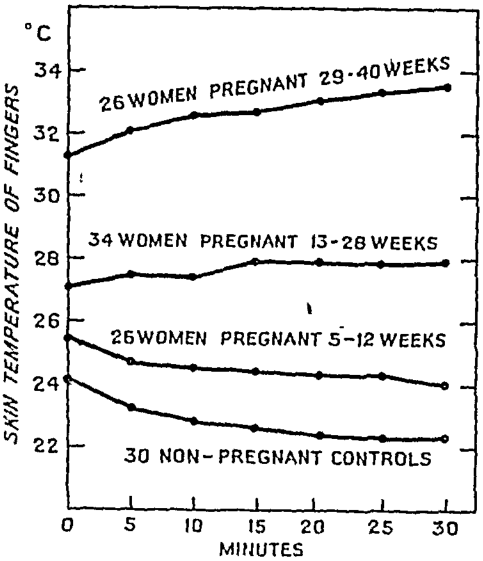

Fig. 2—Average finger temperatures at room temperature of 17°C.

toes there was a slight drop in temperature between thirty-three and thirty-six weeks.

Time of Change in Temperature.—There was a wide scatter in readings; some patients showed full vasodilatation early, others late; but, when the numbers were divided into groups according to temperature level, below 25°C, 25–29°C, and over 30°C (tables I and II) it appeared that the change in vasomotor control involved in this rise in temperature most often occurred in the middle trimester, and at the environmental temperature of 17°C it was much less marked in the feet than in the hands.

Effect of Excitement.—When the average readings during the whole thirty-minute period were considered (figs. 2 and 3), an interesting point emerged. The graph in the non-pregnant controls and that of women in the first trimester showed a slight but steady drop in temperature, whereas in the last trimester there was a slight rise. The change was more evident in fingers than in toes. Only first-visit readings were used for these graphs; therefore any initial vasoconstriction due to nervousness must have applied equally to each group. The slightly lower initial readings shown in the group in the last trimester may have been caused by vasoconstriction due to nervousness. It is unlikely that the controls and women in early pregnancy alone became increasingly nervous during the period of reading; it seems more likely that in them vasoconstriction increased because of the cool environmental temperature. It was noted that any disturbance or questioning caused a slight drop in finger temperature, even in patients whose fingers were becoming warmer (fig. 4), and because of this every effort was made to [illegible] interruption.

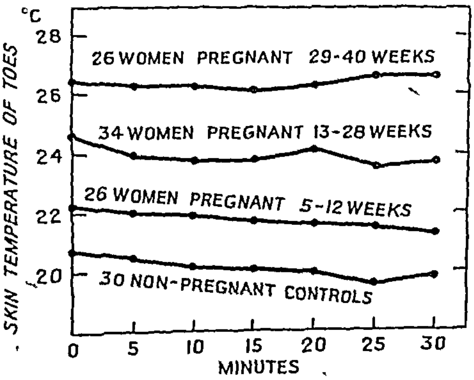

Fig. 3—Average toe temperatures at room temperature of 17°C.

Patients Followed throughout Pregnancy.—In 16 patients records were made at several stages of pregnancy. The finger and toe temperatures in this group closely followed those of the larger group. With slight individual variations, repeated recordings in the same woman produced a similar graph (fig. 5). In this group 4 patients were tested between one and seven weeks after delivery. In 3 of them the average resting finger temperature was 31·5–33·5°C. Normal lactation was established in 2 of these patients at the time of the test. The 3rd mother, whose digital temperatures were recorded seven weeks after delivery, had had to wean the baby three weeks after birth because of insufficient breast-milk, after which inhibition of lactation had been encouraged by taking large doses of Epsom salts. In the 4th patient resting finger temperature in the puerperium was 23·2°C and she complained of a subjective feeling of coldness. In her case vasoconstrictor drugs had not been used after delivery, and normal lactation had been established.

ANALYSIS OF RESULTS

Stage of Menstrual Cycle in Controls.—The day of the menstrual cycle was known in 27 of the non-pre[illegible] volunteers. The average resting temperatures of fingers and toes of 13 women in the first half of the cycle were 23·1 ± 1·3°C (s.e. mean) and 20·0 ± 0·36°C (s.e. mean) respectively. In the second half of the cycle the average finger temperature of 14 women was 21·2 ± 0·76°C, and that of the toes 19·5 ± 0·21°C. The differences are not statistically significant.

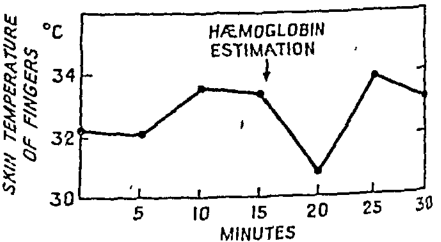

Fig. 4—Example of fall in finger temperature when patient is disturbed.

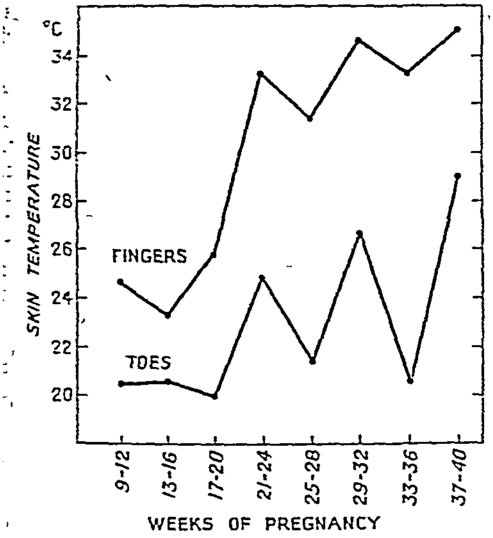
Effect of General Environment.—Since some of the women were inpatients living in a centrally heated building, whereas others were outpatients, it was thought advisable to see if there was any significant difference between the two groups. Those who were seen as outpatients in the later months of pregnancy had slightly lower resting finger and toe temperatures than had the inpatients, but the difference was not significant (tables III and IV.)

Age.—The average age in the non-pregnant controls was 24·9 years, whereas in the pregnant women it was 27·9 in those tested in the first trimester, 26·0 in the second, and 27·7 in the third. No significant difference was found when each group was divided into those aged 25 or less and those aged 26 or more (tables III and IV).

Parity.—No significant difference in finger or toe temperature was found in parous patients when compared with nulliparous patients in the controls or between parous and primigravid patients in the same trimesters of pregnancy (tables III and IV).

Normal Vasomotor State.—All patients were questioned directly regarding (*a*) tendency to have cold hands and/or feet in cold weather, (*b*) incidence of chilblains, (*c*) incidence of vasospastic attacks, and (*d*) subjective temperature changes during pregnancy. 10 non-pregnant women and 56 of the 100 pregnant patients stated that they



. 5—Digital temperatures in a woman throughout pregnancy.

lly had cold extremities in winter, while 9 non-nant women and 34 pregnant ones gave a history hilblains on hands or feet. 12 of the non-pregnant nen and 25 of the pregnant had occasionally noted spastic attacks in one or more fingers. There was ignificant difference in resting finger or toe tempera- between patients with a history of vasospastic cks and those without (tables III and IV).

major degree of vasomotor upset was present in one woman, who was seen in the middle trimester er second pregnancy. Unfortunately she came from stance and could not report again. She stated that re her first pregnancy she had had severe vasospastic cks in the hands. During her pregnancy and in the ter following delivery she had had no attacks, but hands had become very blue. When seen on a cold ter day at the seventeenth week of her second nancy her hands were blue and the resting tempera- was 21·1°C in fingers and 20·7°C in toes, readings h were lower than those of the average at this od. 4 other patients reported freedom from minor spastic attacks during pregnancy; 2 seen in the r months reported continuance of attacks; and ated that they felt subjectively colder as pregnancy anced, but they showed a resting finger temperature ver 30°C when tested during the last trimester. the 100 patients, the number who had noted a subjective feeling of warmth in the present or previous pregnancies was surprisingly small (19), but of the 16 followed throughout pregnancy, who were questioned repeatedly, 13 finally reported a subjective feeling of warmth or stated that they had not noted the cold during the winter. In this group the time of appreciating the change varied from the twenty-first to the thirty-eighth week of pregnancy.

ean values for finger temperature in non-pregnant and pregnant women. The figure following the mean is the S.E. of the mean, and the figure in parentheses is the number of observations on which the mean is based.

PULSE-RATE AND BLOOD-PRESSURE

In the present investigation the average pulse-rate and blood-pressure readings showed a slight drop during the thirty-minute period in non-pregnant and pregnant patients.

At the end of the thirty-minute period the average pulse-rate was 71 in the non-pregnant controls, whereas in the pregnant women it was 75 in the first trimester, 77 in the second, and 83 in the third. In the 13 patients tested during the first two weeks of the puerperium the average pulse-rate was 82.

The final average resting blood-pressure was 109/70 in the non-pregnant controls, 109/66 in the first trimester, 107/64 in the second, 114/78 in the third, and 113/78 in the puerperium.

SUMMARY

At a room temperature of 17 ± 1°C observations were recorded of the resting skin temperature of 30 non-pregnant women, 87 pregnant women, and 13 women in the first two weeks of the puerperium.

In non-pregnant women and during the early weeks of pregnancy the resting toe temperature closely approached that of the environment, whereas the temperature of the fingers was only a few degrees above it.

As pregnancy proceeded, in most of the women the extremities became warmer and did not cool in a moderately cold environment.

This maintenance of vasodilatation in cool surroundings was more marked in the fingers than in the toes.

A slight drop in resting temperature of fingers and toes occurred during the first two weeks of the puerperium, but it did not fall to the levels found in the non-pregnant controls or during the first trimester of pregnancy.

During the resting period there was a gradual drop in the temperature of the extremities in non-pregnant controls and patients in the early weeks of pregnancy, but in women in the later months of pregnancy the resting temperature tended to rise. It is suggested that

this rise may be due to the passing off of an initial slight vasoconstriction due to fear or excitement.

I am much indebted to Prof. Sir James Learmonth and Prof. R. J. Kellar for their help and advice during the course of this investigation, and to Prof. Henry Barcroft, whose specially designed thermocouple was used throughout.

DAVID LEWIS NORTHERN HOSPITAL
(THE UNITED LIVERPOOL HOSPITALS)

THE ability of the prostatic epithelial cell to secrete acid phosphatase has been repeatedly demonstrated (Gutman et al. 1940, Watkinson et al. 1944). Hyperplasia of the prostate gland is often reflected in greater acid-phosphatase activity in the serum, and many clinicians look on a raised serum-acid-phosphatase level as confirming the malignancy, and a low level the benign character, of such hyperplasia.

Though Abul-Fadl and King (1948) and King and Delory (1948) have shown that such a conclusion is not always justified, this test is still being used in the diagnosis of prostatic carcinoma, together with a radiographic search for bone metastases.

THE PLACE OF MICROSCOPY

Microscopy of prostatic tissues, apart from material obtained from endoscopy or aspiration biopsy, should not be regarded as a means of diagnosis but rather as a means of ascertaining the degree of malignancy of excised tumours. Routine microscopy of prostatic adenomata must be extensive if it is to be reliable. To reveal small malignant foci serial sections of the whole of the excised material must be examined. Therefore aspiration biopsy and endoscopy are haphazard methods of obtaining material for histological examination; the specimen obtained is only a random sample of the growth. Adenomata of the prostate are almost always surrounded by a bed of hyperplastic tissue from which further adenomata may arise, or in which malignant foci may remain or develop after prostatectomy. Whereas recognition of the more undifferentiated variety of prostatic carcinoma is relatively easy, the well-patterned adenocarcinoma may present difficulties of interpretation even to the most experienced pathologist. Histological examination is therefore limited in its scope as a precise means of determining the diagnosis and prognosis of any one case of prostatic hypertrophy. Further, as most of the carcinomas of the prostate diagnosed by clinical and radiological means are beyond radical surgical treatment, the histological method often can be used only after necropsy. Its chief value is in the detection of unsuspected early malignancy after surgical removal of a clinically benign gland.

DIFFICULTIES IN DIAGNOSIS

There are three types of case in which the diagnosis is difficult.

(1) The first type is *prostatic carcinoma* unreco able clinically or radiologically, but unexpectedly f to be malignant on histological examination of enucleated specimen. If the serum-acid-phos test was reliable it would be a great help in the operative assessment and the planning of the op in such cases.

(2) In the second type of case neoplastic deposits bone have been discovered radiologically, but the clin evidence that they originated from the prostate inconclusive. The primary lesion may be elsewh and remain undetected, and the radiological app ances may be atypical. Here again the serum-a phosphatase test, if reliable, would be of great value.

(3) In the third type the prostate gland appears t clinically malignant by reason of its hardness, irregula and size; histological examination is not feasi *and radiological evidence of metastasis is not forthcom* In such a case the diagnosis would be clinched by serum-acid-phosphatase test, if reliable.

INVESTIGATION

For these reasons we have reviewed the case-rec of 48 patients admitted to hospital with prostatic hy plasia, and we have tried to assess the diagnostic prognostic importance of the serum-acid-phosph level.

Method.—About half the serum-acid-phosph determinations were done by the phenyl-phosp method of King and Armstrong (1934) and the remai

the formalin-inhibition method of Abul-Fadl and ng (1948). Figures in parentheses in the accompanying les are those obtained with the former method.

Results.—The preoperative serum-acid-phosphatase els, together with the histological findings in 33 cases benign prostatic hypertrophy are set out in table I well as those of 4 cases of histologically confirmed cinoma. It is to be noted that in 3 of these 4 cases adenocarcinoma the serum-acid-phosphatase levels re conspicuously low, and in the 4th the level was ly 4·1 King-Armstrong (K.A.) units per 100 ml.

Table II sets out the details of 11 cases diagnosed and ated on clinical grounds as carcinoma of the prostate which no histological proof was obtained. The gnosis rested mainly on clinical examination of the ostate aided by the estimation of the serum-acid-osphatase level and routine radiography of the lumbar ine and pelvis.

Excluding cases 39 and 42, in which the diagnosis nnot be considered definite, there remain 13 cases carcinoma of the prostate in which serum-acid-osphatase levels were known before treatment with lbœstrol was begun; they were 0·6–103 K.A. units r 100 ml.

DISCUSSION

In this series of cases the serum-acid-phosphatase vel before operation seems to have been of little value differentiating between clinically benign enlargements the prostate and those in which small areas of alignancy were unexpectedly found on microscopy.

In 36 of the cases shown in table I the preoperative iagnosis had been benign adenomatous hyperplasia; of these were found to be of early malignant change. Case 35 had been regarded clinically as malignant The serum-acid-phosphatase level in these 4 malignant cases was 1·5–4·1 K.A. units per 100 ml., and in the whole group 0·3–7·2 units per 100 ml. Of the 42 estimations made in the 37 cases in this group 40 were less than 5 K.A. units per 100 ml. The 2 higher levels were found in the same patient (case 20). The most frequent reading was in the range 0·3–3·0 K.A. units in which there were 31. Low or normal serum-acid-phosphatase levels cannot therefore be taken as evidence of the essentially benign character of a prostatic hyperplasia.

Wray (1945) states that serum-acid-phosphatase levels up to 3·5 K.A. units per 100 ml. are normal; those of 3·5–5·0 K.A. units are significant if there are clinical reasons for suspecting prostatic carcinoma; and those above 5·0 K.A. units strongly suggest prostatic carcinoma. Abul-Fadl and King (1948) maintain that serum-acid-phosphatase levels above 5 K.A. units strongly suggest prostatic carcinoma, and those above 3 K.A. units are suspect, especially after formaldehyde treatment of the serum. These levels have been used for grading prostatic neoplasms preoperatively according to their degree of malignancy. If cases of prostatic tumour associated with a serum-acid-phosphatase level under 5 K.A. units per 100 ml. are regarded by clinicians as benign, errors in diagnosis will inevitably arise.

In the series investigated by Abul-Fadl and King (1948) 8 out of 22 patients with prostatic cancer with bone metastasis had a serum-acid-phosphatase level under 5 K.A. units per 100 ml., and 19 out of 22 patients with prostatic carcinoma without bone metastasis had a level under 5 K.A. units, whereas 6 out of 23 patients with adenomatous hyperplasia of the prostate had a level of 5–21 K.A. units. In view of this wide range it is obviously necessary to exercise great caution in using the serum-acid-phosphatase level for diagnosing prostatic disease. This need for caution is reinforced by the fact that Boylan and Tillisch (1948) found that in 44 out of 100 cases of carcinoma of the prostate with skeletal metastasis the serum-acid-phosphatase level was within normal limits.

Sullivan et al. (1942) suggested that a normal serum-acid-phosphatase level associated with carcinoma of the prostate was due to the anaplastic character of the neoplasm; but in cases 34–37 in the present series the histological pattern was that of a well-formed adenocarcinoma.

In the 12 cases in which prostatic carcinoma had been diagnosed on clinical findings the serum-acid phosphatase level was 0·6–103 K.A. units per 100 ml., but despite this greatly increased range levels higher than 10 K.A. units were found only in 2 patients. In the remaining 10 cases the level was 0·6–7·1 K.A. units which is almost identical with that of the cases regarded preoperatively as benign. In this group 4 cases also showed radiological evidence of vertebral or pelvic metastasis, and in these the level was 3·1–103 K.A. units per 100 ml. In the remaining 8 cases without bone metastasis the level was 0·3–12 K.A. units.

It was in the cases included in table II that the diagnosis was most difficult, because there was usually no indication for radical surgery allowing thorough histological examination of the removed tumour. Radiological evidence of metastasis gives no certain indication of the site of the primary tumour in many instances. According to Willis (1948) the error attached to clinical diagnosis of prostatic hyperplasia is as high as 2 out of 7 cases, based on his series of 31 patients, upon whom very thorough necropsies were done.

In the present series there are 15 cases of carcinoma of the prostate, in 4 of which the diagnosis was confirmed histologically, and in only 2 of which the serum-acid-phosphatase level was higher than that obtained in 33 cases of histological benign hyperplasia—a frequency too small to be of definite help in the individual case.

Wray (1945) and other workers have suggested serial determinations of the serum-acid-phosphatase level as a means of controlling the treatment of prostatic cancer with synthetic œstrogens. This might be feasible where the initial level is high; but, where the initial levels are low, small reductions are insignificant, probably not outside the range of experimental error.

SUMMARY

The preoperative serum-acid-phosphatase levels were investigated in 33 cases of benign prostatic hypertrophy, 4 cases of adenocarcinoma of the prostate, and 11 cases clinically diagnosed as cancer of the prostate with or without metastases in bone.

Prostatic malignant disease was often associated with a normal serum-acid-phosphatase level, and the test was of little value in the clinical assessment of most cases.

A low serum-acid-phosphatase level cannot be accepted as evidence of the benign character of a prostatic tumour.

We are very grateful to Mr. Philip Hawe, F.R.C.S., and to Mr. W. R. Hunter, F.R.C.S., for allowing access to the records of patients under their care.

ACUTE POLYARTERITIS NODOSA IN CHILDHOOD

A. W. TAYLOR
M.R.C.P.
CLINICAL PATHOLOGIST

N. M. JACOBY
M.D. Lond., M.R.C.P.
PÆDIATRICIAN

KENT AND SUSSEX HOSPITAL, TUNBRIDGE WELLS

POLYARTERITIS nodosa, though recognised more than formerly, remains a rare disease. With the ledge that its classical features, such as the subcuta nodules and eosinophilia, are often missing, there been a tendency to diagnose it on insufficient gro The experimental evidence for its allergic origin is unconfirmed, and it may be premature to draw p between polyarteritis nodosa and such conditions anaphylactoid purpura, nephritis, and acute rheumati If all conditions where an allergic element is combi with inflammatory vascular lesions are to be classed varieties of polyarteritis nodosa, then this term will ce to have any clinical value, and the classification of will not be advanced. Nevertheless there seems no doubt that polyarteritis nodosa is sometimes unrecognised cause of grave illness.

In the following case the peripheral vascular predominated in the early stage. The clinical p bore close resemblances to conditions described other names.

CASE-HISTORY

A girl aged 7 years was admitted to the Kent and S Hospital in the early afternoon of Aug. 10, 1948. She been quite well until two weeks previously, when she a sore throat and fever. This responded to sulphonam about five days. Two days before admission, she of aching legs. On the day of admission she co nausea on waking. During the morning she vomited times and it became apparent that her face was swelling. midday there was well-marked œdema of the cheeks orbital region. There was slight epistaxis, after which vomit was bloodstained. She had passed some clear on waking, but none since. There had been no melæna.

Previously she had had measles, whooping-cough, and chickenpox, but none severely. The rest of the family, including her two sisters, was quite well. Their diet included plenty of fresh fruit and vegetables.

On examination the child was drowsy but conscious. Bo eyelids were ecchymotic and swollen. The palpebral fissu were occluded and could not be opened even with pressu The cheeks and the upper lip were œdematous and shiny an did not pit on pressure. Blood oozed from the left palpe fissure and both nares. The pulse was slow and regular an the blood-pressure 118/60. There was nothing abnormal chest, heart, or abdomen. A blood-count showed: hæmoglobin 88%; red cells 4,380,000 per c.mm.; platelets 80,000 per c.mm.: white cells 32,000 per c.mm. (polymorphonuclears 86%). Ascorbic acid 500 mg. and vitamin K 10 mg were given intramuscularly.

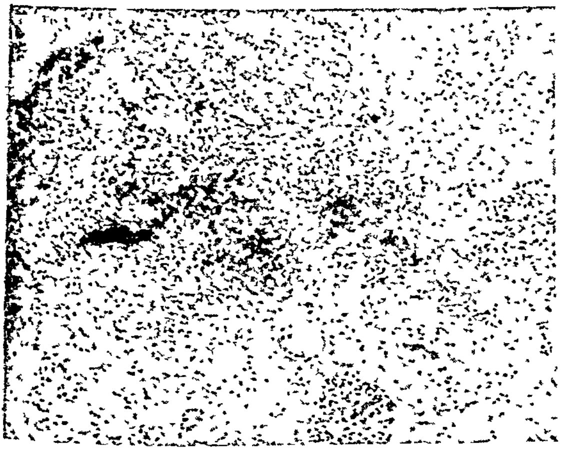
By 9 P.M. on the same day, the facial œdema had increased, and the bleeding continued. The blood-pressure was 138/80. One pint of stored blood was given by intravenous drip, and subsequently the infusion was continued with 5% dextro in 1/5 physiological saline. Penicillin was given intramuscularly, 150,000 units four-hourly. At midnight it was noticed that the feet had become blue, cold, and œdematous. The discoloured area involved the whole of the foot and ankle and had a sharply demarcated upper edge.

On the *second day* the facial œdema did not increase, but a blue staining appeared, which became progressively deeper in colour. The bleeding from the palpebral fissures and the nares continued slowly but steadily. There was occasional vomiting of bloodstained mucus.

Since admission, we had been anxious to examine the urine, but none was passed. There was no evidence of distension of the bladder, and it was recognised that the child had either partial or complete suppression of urine. A catheter was passed and 2 oz. of bloodstained urine was obtained. It contained red blood-cells, pus cells, and granular casts. At subsequent intervals a catheter was passed again, but, as no more urine was obtained, steps were taken to re-establish ion of urine. At this stage the blood-urea was 265 mg.)0 ml. and the intravenous infusion was therefore changed % dextrose. On several occasions 20 ml. of 50% dextrose given intravenously. But none of these measures was ssful.

the *third day* the face showed a "butterfly" area which lmost black. The hæmoglobin had fallen to 48% and a er pint of blood was given. At this time thrombocytes 100,000 per c.mm., and bleeding-time was over 12 tes; coagulation-time was normal.

the *fourth day* there was little change. The blood-urea 58 mg. per 100 ml. As the suppression of urine remained ute it was decided to use peritoneal dialysis, in the hope it would tide the child over until the kidneys recomed secretion. Under local anæsthesia, a small abdominal r and cannula was inserted into the peritoneal cavity, e left iliac fossa. About 750 ml. of 10% dextrose solution un in during about 20 min., using an ordinary infusion olitre' drip-chamber and rubber tubing which was ected to the cannula. The rubber tubing was then ped. After an hour the fluid was siphoned off. The urea nt of the fluid obtained varied between 0 25 and 0·44%. procedure was carried out twice daily and the amount fluid which siphoned back approximated to the amount in on each occasion.



1—Section of kidney showing acute necrosis of arteriole, with surrounding hæmorrhage. (× 85.)

)n the *fifth day* the blood-urea had fallen to 188 mg. per ml. and the feet were warmer and less blue.

)n the *sixth day* the child, who had been remarkably scious all the time, relapsed into coma. Her blood-urea now 376 mg. per 100 ml. After two fits she died.

Necropsy.—The orbits were filled with hard coagulated sses of blood, and attempts to remove a globe by dissection ved futile, because tissues could not be differentiated. The heart and lungs appeared normal. The peritoneal cavity wed only the entry marks of the cannula used for dialysis: re was no evidence of peritoneal infection. The spleen was larged to about three times the normal size and showed eral small infarcts. The kidneys were swollen and intensely morrhagic; the cut surface was much congested, with any hæmorrhages; the capsule stripped easily. The suprapal glands were not affected. The bladder was empty, and ere were no other abnormalities of the renal tract. Other scera appeared normal.

On removing the brain, it was found that the hæmorrhage d extended over the whole of the anterior fossa, but mained entirely extradural. The brain itself showed only me flattening of the convolutions, consistent with increased tracranial pressure. No evidence could be found of thrombi any large vessels.

Histology.—An acute arteritis involved arteries and arteriles extensively, with complete necrosis of the affected segnents of the vessels and much resulting hæmorrhage into urrounding tissues. The lesions were most widespread in the idneys, where the effect was one of almost complete infarction of both kidneys. The spleen was also widely affected. Figs. 1 and 2 show typical lesions. The picture was that of acute polyarteritis nodosa, and the lesions were identical with those frequently described in this condition.

DISCUSSION

This case presented difficulties in diagnosis. The main signs were those of multiple spontaneous hæmorrhages into the orbits and soft tissues surrounding the eyes, with epistaxis and hæmatemesis. There followed rapidly subcutaneous hæmorrhages over both feet and ankles, and an absolute anuria which ultimately proved fatal. The histological picture in tissues removed at necropsy was that of acute polyarteritis nodosa. Our purpose in recording the case is not only to draw attention to a dramatic variety of a disease whose clinical variations are endless, but also to suggest a common pathology for clinical conditions described under several different names.

Miller and Daley (1946), in their excellent review of polyarteritis nodosa, list some of the commoner skin manifestations of the disease, including erythema, urticaria, vesicles, bullæ, purpura, and ecchymoses, with such complications as necrosis, ulceration, and gangrene. They point to the origin of skin ecchymoses from rupture of subcutaneous aneurysms, and emphasise the increased incidence of purpuric skin eruptions and peripheral gangrene in childhood. Melczer and Venkei (1946), in a comprehensive review of the skin manifestations of polyarteritis nodosa, give a good account of the histology of the condition and describe new cases of multiple, often symmetrical, ecchymoses, followed by gangrene. They lay stress on the diagnostic importance of a prolonged bleeding-time associated with a normal platelet-count. Vining (1938) describes a case of proven polyarteritis nodosa in childhood where subcutaneous nodules complicated by gangrene occurred on the nose and shoulders, and where recovery followed a long illness. Sheldon (1947) describes under the name of purpura necrotica a syndrome seen in three children where the main features were symmetrical ecchymotic lesions leading to necrosis and separation of the sloughs: the depth varied from necrosis of the superficial layers of the skin to lesions involving deep muscle layers with resultant severe scarring. All three patients recovered and no histological examination was possible. From the description of the cases, however, it seems highly probable that the condition was again polyarteritis nodosa. Sheldon compares his cases with one reported by Beinhauer (1929) who described in a child aged 2 years a fatal purpuric condition which progressed to gangrene affecting areas in both thighs, buttocks, the left elbow, and the right hand. The condition was termed "purpura hæmorrhagica gangrenosa," but the photomicrograph reproduced in the paper is strongly suggestive of polyarteritis nodosa. In this

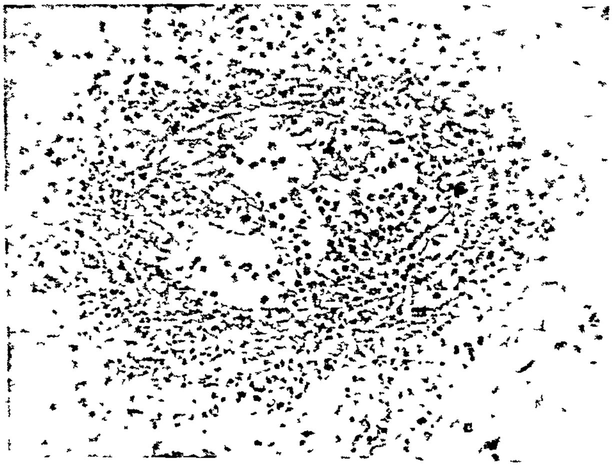


Fig. 2—Transverse section of arteriole in spleen showing acute necrosis. (× 295.)

case, as in Sheldon's, infection of the upper respiratory tract preceded the onset of purpura by 10–21 days.

Closely related to these cases are the rarely recorded cases of purpura and gangrene complicating scarlet fever. Hoyne and Smollar (1941) collected 17 recorded cases of gangrene following scarlet fever, and gave a description of a new one in a child aged 4, with symmetrical gangrene of both feet, developing in the third week of scarlet fever. Following amputation, section above the level of gangrene showed a severe arteritis apparently identical with polyarteritis nodosa.

In postscarlatinal gangrene massive purpuric and ecchymotic lesions are frequently described as preceding the onset of gangrene. The maximal incidence is in childhood. Here then appears a clear link with another rare condition—purpura fulminans. This severe form of purpura, originally described by Henoch, appears from time to time in the literature, usually as a severe complication of scarlet fever. Heinild (1947) in recording a fatal case in a child of 3 weeks emphasises the ætiological rôle of scarlet fever, the purpuric condition developing 2–4 weeks after the rash. He describes the violent bluish-black infiltrated ecchymoses, surrounded by a red halo, as specific of streptococcal sepsis. Henoch's strict diagnostic criteria of a violent ecchymotic eruption proceeding rapidly to a fatal conclusion and never associated with mucosal or internal hæmorrhages have had to be abandoned because an increasing number of cases have been reported, and it is now agreed that the condition is not always fatal, may be associated with hæmorrhages from mucous membranes or internal organs, and is sometimes followed by gangrene in the affected regions. It is clear that this condition can no longer be separated from postscarlatinal gangrene.

These descriptions have so much in common that they seem to refer to a single clinical entity, with minor variations. The patient is usually, but not always, a child, and the illness usually follows 10–21 days after an upper-respiratory infection—usually streptococcal and often scarlet fever. The main features are sudden extensive, commonly symmetrical, ecchymoses of the skin, often involving the extremities, and in the more severe cases followed by local gangrene. There may be associated hæmorrhages from mucous membranes or internal organs. There is little or no deficiency in blood-platelets, but a prolonged bleeding-time is sometimes found. The course is variable: in some cases it is short and fatal, but in others it is long and stormy, with relapses not uncommon. The histological findings, where reported, are those of an acute arteritis, the lesions being characteristic of polyarteritis nodosa. The condition must be regarded as an acute variety of this disease, in which the peripheral arteries and arterioles often bear the brunt of the attack.

Our case exemplifies most of these features but is unusual in that there was very severe involvement of the internal organs, especially kidneys and spleen. A similar complete anuria following almost complete infarction of both kidneys has been described by Rodnick and Davidsohn (1942) in an adult.

SUMMARY

A case of acute polyarteritis nodosa in childhood is described.

The relation between this condition, purpura fulminans, postscarlatinal purpura and gangrene, and purpura necrotica is discussed, and a common ætiology is postulated.

CHOICE OF A TEST-MEAL

J. N. Hunt
M.B., Ph.D. Lond.
LECTURER IN PHYSIOLOGY, GUY'S HOSPITAL MEDICAL
LONDON

TEST-MEALS offer the most direct method of gating simultaneously the emptying and the the stomach. In this laboratory the development new method of investigating gastric activity which the amounts emptying and amounts secreted to measured made the choice of a test-meal a problem of surprising difficulty. We wished to a standard meal which would minimise the between individual subjects in emptying and The factors which led to the final choice are below.

PHYSIOLOGICAL CONSIDERATIONS

It is customary to divide gastric secretion into th phases according to the origin of the secretory stimul the psychic or appetite juice flows first; then the of the gastric phase; and finally the juice of the phase.

The amount of appetite juice is believed to vary w the palatability of the meal. No matter what mea chosen, the psychic response to it will vary in differ subjects. To reduce this variation as far as possi the meal should engender neither profound pleasure distaste: it should have the bland quality of pota rather than the emotional atmosphere of oysters. S a choice provides a small stable psychic stimulus w relatively little influence on the total amount of gas juice secreted in response to the meal.

The gastric phase of stimulation is believed to h two components: (1) mechanical, the result of distens of the stomach by the meal; and (2) chemical, result of stimulating substances present in the meal.

In order to simplify interpretation, it is desirable eliminate one variable. In an investigation desig to measure gastric emptying it would be impracticabl reduce to a minimum the volume of the meal. It is theref necessary to minimise the chemical stimulus. This be achieved by ensuring that the meal contains substances known to cause gastric secretion as a res of their chemical qualities—e.g., protein derivativ Since the intestinal phase is also believed to result fr chemical stimulation, such a meal would be expect to have a minimal stimulating effect from the intes But an effective stimulus is desirable to secure measura volumes of secretion. To achieve this, the volume the meal must be as large as is compatible with a maxim response and the tolerance of the subjects. Thus large bland meal might be expected to owe its stimulat effect mainly to mechanical distension of the stoma and little to chemical and psychic stimulation.

PHYSICAL CONSIDERATIONS

These physiological considerations are a guide to t choice of a meal but there are other, more practic considerations. The test-meal must be recoverable a should allow quantitative estimation of the constitue of the gastric secretion. Unless the meal is fluid becomes liquefied in the stomach, it will not be recov able through a tube which the average subject w tolerate. If the aim is to recover large quantities of meal in a short time, its viscosity must be such as allow this without suction dangerous to the gast mucosa; and our investigation called for a meal of l viscosity, to ensure thorough mixing in the stomach. the other hand, the meal should be somewhat visco since watery fluids tend to leave the stomach re quickly without allowing enough time for the investigati

-tric function. Thus a balance must be struck m a fluid of high viscosity and a watery solution. choice of an agent to render the test-meal viscous icult. No protein matter can be used for this se since it would be digested by gastric juice and oducts of digestion would inactivate the proteolytic es; and thus estimation of the enzymic activity secretions entering the stomach would be prevented. ermore, any digestion of protein or other substances alter the osmotic pressure of the gastric contents. , if the osmotic pressure of the test-meal is to be s an experimental variable, any substance which en down in the stomach must be excluded. Thus , alginates, or gruel are unsuitable.

viscosity of the meal should be uniform and lucible; in order that other workers may use the meal the substance responsible for the viscosity l be widely available in pure form, and it must not re with the estimation of any dyestuff incorporated.

CITRUS PECTIN

far no substance has fully satisfied these criteria; trus pectin, which has been used in our investigation, een found satisfactory.

tin is not broken down by treatment with gastric for 24 hours; it does not reduce the proteolytic ty of gastric juice except by dilution; it does not b hydrogen or chloride ions; and from a single sample it has proved possible to make up solutions viscosity has not varied by more than ± 10%. viscosity has been measured in absolute units, so by trial and error a comparable solution could be in other laboratories. Pectin has not interfered the estimation of phenol-red incorporated in the

the other hand, pectin has its disadvantages. not possible to make up a homogeneous solution except a mechanical mixer. It is not a pure substance, samples being contaminated with glucose, citric a small amount of chloride, and possibly other ances. Its viscosity is influenced by temperature, viscosity at 37°C being about half that at 20°C. lly, a solution does not keep at room-temperature more than 24 hours, fungi and acid-producing bacilli ng it an admirable culture-medium. However, with ol-red such contamination is readily detected by ge in the colour of the dye.

ne of the subjects has been enthusiastic over the ability of the pectin solution even after the addition gar and flavouring; but, although its bland texture ther cloying, no-one has complained of its taste. ral subjects have commented on their intestinal being after the meal.

sides viscosity, probably a number of other factors e meal affect the response of the stomach. Certainly osmotic pressure is important in determining the of emptying and probably also the secretory response. e is a tonicity which gives a maximal rate of empty- From experiments made with gruel fractional meals this appears to be produced by sucrose when depression of freezing-point is about 0·2°C.[1] But is not a suitable depression of freezing-point for a meal which is to be used in investigating the influence smotic pressure on gastric activity; the stomach to the test-meal secretions which depress the zing-point of the gastric contents to 0·4–0·5°C. ng to individual variation in the volume of juice eted it would be impossible to standardise the city of the gastric contents with a meal having a ression of freezing-point of 0·2°C. In preliminary eriments it was found that the depression of freezing- t of the gastric contents towards the end of a gruel l tended towards 0·4°C. It was therefore desirable to strike a balance between a depression of 0·2°C, giving rapid emptying, and one of 0·4°C, with an osmotic pressure least influenced by added secretions.

It has also been shown that solutions with a high osmotic pressure inhibit gastric secretion. The depression of freezing-point of the pectin test-meal—0·3°C—is believed to be below the threshold of the receptors for this response.

The final pectin test-meal used in our investigation contains 20 g. of pectin, 35 g. of sucrose, 60–70 mg. of phenol-red, and sufficient caustic soda to raise the pH to 6·5 in a litre of distilled water. In practice this test-meal has proved very satisfactory.

SUMMARY

Physical and physiological factors in the choice of a test-meal are discussed.

Pectin has proved satisfactory for rendering the test-meal viscous.

Preliminary Communication

A POLYTHENE SUBSTITUTE FOR THE UPPER TWO-THIRDS OF THE SHAFT OF THE FEMUR

There are occasions when it may be desirable to use an internal prosthesis to replace bone. Plastic substitutes have already been used with some measure of success for the head and neck of the femur, the carpal lunate, and the mandible. This preliminary communication is concerned with the more ambitious substitution of a plastic model for the upper part of an abnormal femur; metallic substitutes have already been used.

A boy, 12 years old, was admitted to hospital with a long-standing chondromatous dysplasia of the femur and tibia on the same side; its exact nature is not immediately relevant. We and our colleagues agreed that the only satisfactory treatment was amputation through the hip-joint. But an artificial limb for such an amputation is at best a poor affair, and we welcomed the suggestion made by Mr. K. I. Nissen that an attempt

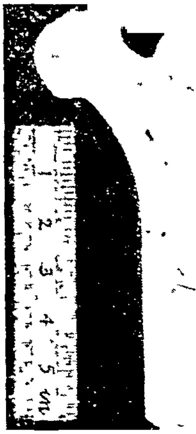

Fig. 1.

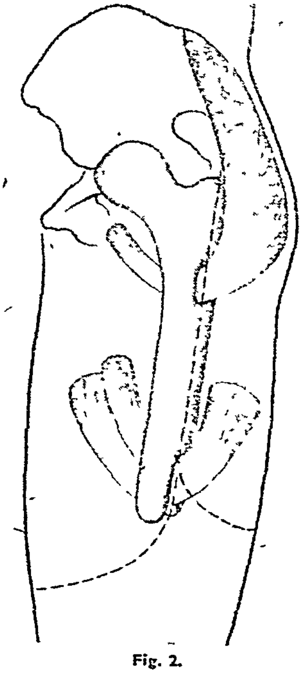

Fig. 2.

Fig. 1.—The polythene prosthesis.

Fig. 2.—Diagram of the prosthesis in position.

should be made to amputate the limb through the middle third of the thigh, fillet out the femur, and substitute for it a plastic model of its upper half or two-thirds. This was done. Precise measurements of the normal femur were first obtained from radiographs taken with precautions to avoid magnification and distortion.

'Polythene' was chosen as the material for the prosthesis on account of its satisfactory mechanical and chemical properties. Superficial alterations can readily be made at the time of operation, which is hardly possible with more rigid materials such as 'Vitallium' and 'Perspex.' Polythene is a straight-chain (aliphatic) hydrocarbon containing 1000–2000 carbon atoms and having only about one double bond; it therefore has the stability and high resistance to chemical change characteristic of the ordinary paraffins, and it also possesses considerable toughness and resistance to fatigue strain. It further resembles paraffin wax in that it has a non-wettable surface and that living tissue does not adhere to it. Polythene has already been used in the human body, animal experiments having demonstrated its inertness and lack of toxicity.

The prosthesis (fig. 1) was carved from a block measuring 10 by 4 by 3 in.; when finished it weighed $7^{1}/_{2}$ oz. and was 8 in. long. Channels were made in the prosthesis for the attachment of the flexors and extensors of the hip, the adductors, and vastus lateralis. From the nature of the deformity of the femur it was obvious that the abductors of the hip would be useless, so no provision was made for attaching them to the prosthesis.

The operation was performed on Aug. 2, 1949, by H. J. S. assisted by J. T. S., Mr. M. Albert, and Mr. D. Evans; the anæsthetic was given by Dr. M. V. H. Denton, and during the course of the operation two pints of blood were transfused. The steps (fig. 2) were as follows:

1. The external iliac artery was exposed and was then occluded by a loop of tape until the greater part of the operation was over.
2. The usual long anterior and short posterior curved incisions for amputation through the lower third of the thigh were made, their lateral junction being continued as a longitudinal incision up to the trochanter.
3. The lateral incision was deepened posterior to the vastus lateralis and the femur dissected out by peeling off the muscles with diathermy cutting. The flaps were completed and all vessels tied distally so that the vascularity of the flaps would be as great as possible.
4. The prosthesis was then inserted, after a good fit of the head of the "femur" had been obtained by filing its surface. The tendon of the iliopsoas was led through the canal in the upper part of the prosthesis and sutured to the tendon of gluteus maximus. The lower margin of the adductors was similarly attached to that of vastus lateralis, the point of attachment lying in the slot cut in the lower end of the prosthesis. By these means the prosthesis was secured effectively, and there seemed some prospect of its becoming well controlled by the more important muscle-groups.
5. The remaining muscles were brought together with interrupted sutures, and the skin likewise, around corrugated rubber drains inserted at the upper and lower ends of the longitudinal incision.

The operation, which lasted for two hours, was a formidable affair and during the last thirty minutes the patient's condition gave us some anxiety. However, with the aid of another pint of blood after operation, he improved rapidly.

Our chief anxiety was the avoidance of infection, for an enormous area of tissue was exposed during the course of the operation. Intramuscular injections of 40,000 units of penicillin four-hourly were therefore given from July 29 (four days before operation) until Aug. 26. Even so there was a little deep infection of the end of the stump and a terminal slough 2 by 1 in. in diameter. Pyogenic staphylococci were found in the discharge, as well as in the patient's nose during the third week after operation, and although these organ sensitive to penicillin it was decided to change to mycin (to which they were also sensitive) in view disturbing persistence of diffuse tenderness and Systemic streptomycin was therefore given at of 1 g. a day for one week. By Sept. 2 the healthy and the ulcer at its tip almost healed; usual after-treatment for an amputation thigh was started.

On Sept. 22 the state of the stump was normal boy has been measured for an artificial limb already walking on a temporary pylon.

We are greatly indebted to Imperial Chemical Ind Ltd. for supplying the block of polythene and de Havilland Aircraft Company for their help in mak radiographic measurements.

ROYAL SOCIETY OF MEDICINE

Whither Antenatal Care?

AT a meeting of the section of obstetrics on O with Mr. LESLIE WILLIAMS, the president, in the a discussion on antenatal care was opened by Mr. BOURNE.

Mr. Bourne said he had been asked to keep the sion on a higher plane, so he deliberately avoided The recorded history of antenatal care went b Aristotle, but it was Pinard who laid the real found Pinard opened a home for abandoned pregnant in Paris in 1895 and noted an improvement in the whose mothers came under his care. Ballant Edinburgh had often been called "the father of ant care"; but this was inaccurate, for his main i was in stillbirth and fœtal abnormality. He was obstetrician, but rather a teratologist; he ha interest in antenatal health than in the deformed It was in later years that he instituted the syst antenatal visiting, and such a system had alread started some years before in Boston.

Mr. Bourne went on to recall how, in 1909, wh was a student at Queen Charlotte's, a small clinic was started by Harold Waller and others attention was focused first on presentation, secon the contracted pelvis, and thirdly on albuminuria an attempt was made to forestall dystocia. The 1914–18 checked progress; but in 1918 the Minis Health began to establish antenatal clinics, and were now over 1600 throughout the country. He d the history of antenatal care into four phases: (1 from Aristotle to Pinard; (2) that introduced by P (3) that introduced by Ballantyne; and (4) that ini at Queen Charlotte's Hospital.

Until lately the emphasis had been more on str than on function, except in regard to albuminuria. mechanical view encouraged unnecessary interf —for example, induction of labour where the hea high. Herman had even given a list of the peri gestation at which induction should be carrie according to the size of the conjugate. Inducti Krause's bougies was the usual method. Between and 1921 the induction-rate at Queen Charlotte' risen from over 2% to over 7%, and the maternal mor had steadily risen to 4·41 per 1000 in 1934, which w highest recorded since 1890. This was despite incr antenatal care and better obstetrical training. It appear therefore that up to this point antenatal car failed in its primary object. But much of this mor was due to mismanagement in labour. In the external pelvimetry came to be regarded as useless the mechanists got further encouragement from introduction of X-ray pelvimetry. Mr. Bourne dep the practice of basing obstetrical prognosis on radiological findings, and pointed out that the f normality were far too narrow ; moreover. many actors—notably the ability of the uterus to t—had to be taken into account.

function was all-important. could this be pre- r ensured ? Mr. Bourne felt that it could. Func- ction of the uterus depended primarily on the 's emotional reaction. and secondly on the type ent : and he contrasted the gynæcoid with her riods. her ready conception. her effortless preg- and her eutocia with—at the other extreme—the type with her menstrual difficulties. her unsatis- obstetrical history, and her liability in labour to num of pain with a minimum of effective function. gnancy unresolved fear was bound to lead to Physical constitution could not. of course. be ; but much could be done with regard to fear. hould if possible be exorcised during pregnancy. in secure good uterine function. Short of moderate rition, he did not think that diet had much effect ine function, except in the matter of premature The chief value of antenatal exercises depended gestion and the feeling engendered in the patient e was contributing towards her labour. The e results of X-ray pelvimetry and other structural d been overemphasised at the expense of function.

W. C. W. NIXON urged that the mechanistic ch should be replaced by the holistic. Dr. Wrigley inted out that meddlesome midwifery had spread he labour ward to the antenatal clinic. It was m who had coined the term "constructive e" in relation to pregnancy. and the new attitude natal care was born in those days. Professor Nixon ed the persistence in midwifery teaching of sis on the abnormal. A food advice bureau. such been established at University College Hospital. necessary part of an antenatal clinic. Nutritional a still prevailed. and all cases should have a routine tion of their hæmoglobin at their first attendance ain at 36 weeks. This would help to reduce post- hæmorrhage and its effects. X-ray examination chest was done as a routine at University College al. and this should be obligatory. He advocated l version as a matter of course. where needed— n anæsthetic only when an attempt without an etic had failed. One of his main concerns was the tion of fear. and classes of training organised by esthetist to the obstetric unit did much to engender nce. These courses were run in coöperation with iotherapist and a labour-ward sister. The physio- ist talked of the value of relaxation as indicated ntly Dick Reid. Breathing, posture. and exercises all influence labour favourably, and the exercises ere those of Mrs. Helen Herdman. These ideas iginated in Britain. but they were already better ted in the U.S.A.

A. J. WRIGLEY suggested that in the past the t's general health had too often been ignored : and lored the practice whereby one worker did all the esting, another rushed round with a sphygmo- neter, and another laid hands on the abdomen. t none took any notice of the patient as a person. to results from remedial exercises were discour- ; two investigations had shown that these exercises o significant effect on the nature or outcome of . As regards version, this was seldom necessary the 34th week ; no force should be used. parti- y if the patient was anæsthetised. Dr. Wrigley ed pointless and ineffective inductions for alleged aturity, and held that less attention should be to the breast in pregnancy. Without wishing to be d as a mechanist, he felt that all primigravidæ l have X-ray pelvimetry. In antenatal clinics routine practices could be replaced if more common were used. He referred to the present detachment antenatal officer from the hospital officer as a great hich had evolved fortuitously with the growth of atal clinics ; under the National Health Service etachment was being aggravated—not abolished as een hoped—owing to the division of responsibility en the local health authority and the regional tal board.

ARNOLD WALKER welcomed the provocative note Dr. Wrigley had introduced. He pleaded for less condemnation of the work of antenatal officers. Nobody thought this system perfect, but it was the only way to fill an otherwise inevitable gap. Welfare-mindedness was the spirit and essence of antenatal clinics. and it was backed by a knowledge of local conditions. These clinics should be integrated with the hospitals. though this would not be easy. In the clinics it was better to have routine than serious omissions.

Mr. A. W. PURDIE said that the system of antenatal clinics worked well ; but the system might break down through routine ; toxæmia might be missed because supervision automatically ceased when the patient outran her theoretical gestation period.

Mr. J. M. WYATT thought that much fear was engendered by the publicity given to the difficulties of labour and all the measures to which the patient was subjected to forestall these difficulties. The greatest source of reassurance was the successful multipara who had weathered six or more pregnancies without difficulty.

Reviews of Books

The Mammalian Adrenal Gland

GEOFFREY H. BOURNE, D.SC., D.PHIL., reader in histology in the University of London at the London Hospital Medical College. London : Oxford University Press. 1949. Pp. 239. 30s.

Dr. Bourne's book is a well-documented comparative study of the anatomical position and histology of the mammalian adrenal. It is introduced by a historical review of the gland and its histology. and contains descriptions of the adrenals of more than 250 species. Many of the descriptions of the adrenals of the eutherian mammals have been collected from published work. and so are less complete than those derived from Dr. Bourne's own observations (which are particularly extensive on the marsupials). His study demonstrates that the mammalian adrenal displays a remarkably constant structure, and he concludes that an adrenal gland in which the medulla is in the main completely separated from the cortex. and surrounded for at least three-quarters of its circumference by the latter. is as diagnostic of the mammalia as hair and nails. Only in the monotremes does the adrenal differ from the typical mammalian type. The book ends with a general summary of mammalian adrenals, including concise observations on the lipoids, pigments, and vitamin C of the adrenal. and the relation of adrenal cortical structure to function.

A Twentieth Century Physician

Being the Reminiscences of Sir ARTHUR HURST, D.M., F.R.C.P. London: Edward Arnold. 1949. Pp. 200. 15s.

WHEN Sir Arthur Hurst died he left behind him his autobiography in the making. Now, after four years. with the help of his friend Prof. John Ryle, it has been completed. If he had been given time Hurst would no doubt have expanded the account here given of his later activities to the scale on which his earlier life is presented. Had he done so the story might have gained in completeness but perhaps not in interest. For it is of the young. vital, ardent Hurst that we may be content to read. before his asthma had taken toll of his incomparable energy and vitality. Nothing that he ever did. or wrote. was dull or colourless. and here is the authentic voice of his early days, with its curious deep buzzing note of eager interest, determined to expose what he knew to be error and to demonstrate what he held—not always correctly or for very long—to be truth.

Autobiography is apt to unfold itself on a fixed pattern : childhood's memories. school. college. initial difficulties and setbacks, recognition and reward. Hurst's does not differ from others except that there were no initial difficulties, and no setbacks in the astonishing burst of success which was his from the first, and of which he here makes so little. For within a few years he became not only a consultant whose opinion was widely sought. but the most popular and inspiring teacher of his great medical school and an acknowledged leader in the investigation of disease by the newer methods. For a variety of reasons, at the turn of the century. medicine in this country was in some danger of stagnation, and Hurst was one of those who did much to restore the strong current.

As in all good autobiographies there is considerably less about the writer than about those with whom he came in contact. On almost every page are set inimitable little sketches of his teachers, colleagues, and fellow workers which one feels are true without being unkind—of Babinski for example, or Jacobson, Fripp, James Mackenzie, or Parkes Weber. His own rich and varied personality found expression in irregular features of extraordinary charm; so it is not strange that the two great artists whom he numbered among his friends lost no time in deciding that he must sit for them. Had it not been for Sir William Rothenstein's perfect sketch, Herkomer's fine portrait might seem altogether satisfying. Both show him as he was when young, and both are admirably reproduced in the present volume. All who knew Hurst and many who did not will enjoy the gay easy flow of his memories of a memorable life.

Coronary Artery Disease

F. P. Boas, M.D., associate physician, Mount Sinai Hospital, New York; N. F. Boas, M.D. Chicago: Year Book Publishers. London: H. K. Lewis. 1949. Pp. 399. 33s.

The subject of coronary disease is now so large that even a book of this size can cover only the essentials. It opens with brief accounts of the anatomy and physiology of the coronary arteries. Their physiology, indeed, is still little understood, and hence the mechanism of many cardiac pains cannot be explained. In discussing the drugs reputed to improve the coronary circulation, the authors can make out a good case for none but the quick-acting nitrites. Their account of the effects of coronary disease does little to clear up the confused terminology of our day. Thus "angina pectoris" is used for cardiac pain of effort, the term "coronary insufficiency" is condemned but retained, and "benign heart pain" is applied to pain which is not of cardiac origin. However, the descriptions of the clinical pictures are good and will help the practitioner in his essential problem—diagnosis.

Medical Clinics on Bone Diseases

A Text and Atlas. (2nd ed.) I. Snapper, M.D., clinical professor of medicine, Columbia University, New York. New York and London: Interscience Publishers. 1949. Pp. 308. £6.

The new edition of this work emphasises afresh the extent to which our knowledge and conception of diseases of the skeleton have changed in the last twenty-five years. Clinical investigation and clinical observation have repeatedly demonstrated that a close relation exists between general medicine and many diseases of the bones. Too often a monograph on skeletal diseases is a dull collection of weird cases published by an author who lacks the power of critical thought and who knows little of the rapid advance of medicine. By contrast, Professor Snapper's monograph has the refreshing air of a work undertaken by a master of modern medicine who has studied bone diseases according to a well-considered plan. His work ranges over a long experience in Amsterdam, Peiping, and New York, and shows the constant application of a lively intelligence, kept up at one time despite the worst cruelties of war. He delights in unfolding the complicated story of calcium and phosphorus metabolism and how it is related to hyperparathyroidism, osteomalacia, rickets, and the various types of osteoporosis. In doing this he shows equal skill in explaining histological and biochemical detail.

The whole book has been rewritten and rearranged. The chapter on hyperparathyroidism has been subdivided into four parts, and new ones on osteoporosis circumscripta cranii, leontiasis ossea, neurofibromatosis of the bones, and the skeletal lesions in lymphosarcoma, Hodgkin's disease, and hæmolytic anæmias have been added. Polyostotic fibrous dysplasia of the bones has been separated from lipoid granulomatosis of the bones, and the skeletal changes in leukæmia have been separated from multiple myeloma. There are 46 plates reproducing 264 illustrations, and 234 of these are true photographic prints.

For every condition ætiology, biochemistry, anatomy, histology, experimental data, sym radiological findings, diagnosis, and treatment fully considered. Statements made in the critically examined and each chapter has a full graphy. Those American doctors who are to think of morbid histology as an effete pastime can congratulate themselves that a ph *thoroughly trained in the European method* is their midst.

It seems curious that Professor Snapper has had no tunity to study the Fanconi syndrome, and it is to be that cases will be sent to him in New York in time for edition of his monograph. This form of osteomalacia is identified because of the associated renal it is evidently due to incompetence of the renal reabsorb glucose, amino-acids, and phosphates. gross deformities resulting from osteomalacia, fibrosis of liver may develop, and this sometimes leads to pri carcinoma of the liver. There is no other known con in which persistent amino-aciduria occurs; and al twelve different amino-acids have been identified in the of various patients—a partial revelation which could fascinate the agile mind of this author.

This monograph is a masterpiece. Most medical students will pass it by as too detailed for liking; postgraduate students will devour it; general practitioner will never find time to read it the orthopædic surgeon will say that he does not stand it. But for the physician it is a feast.

Modern Practice in Anæsthesia

Editor: Frankis T. Evans, M.B., F.F.A.R.C.S., anæsthetist, St. Bartholomew's Hospital, Lon London: Butterworth. 1949. Pp. 566. 50s.

Before even a line is read, both the eye and hand delighted with this book. It is a standard work reference, and must surely become indispensable *everybody interested in anæsthesia.* The scope frankly limited to clinical anæsthesia; so the resea worker in allied fields, seeking experimental statistical information, may be disappointed. For anæsthetist in training, however, or for the physic with an anæsthetic problem, the book is authoritati complete, and essentially practical. Dr. Frankis Ev has almost succeeded in the difficult task of maintain a uniform standard among his team of writers. A rat condensed and somewhat limited chapter on anato may well be the result of inadequate briefing, for author himself is not an anæsthetist: more topographi details of the nervous system are needed, as a guide regional anæsthesia, and this section deserved fuller better illustrations. A more serious falling off from general standard is to be found in the chapter apparatus: it is hardly enough to give a superfic description of the machines on the market today, and a book of such standing a more learned treatment needed of the mechanical, physiological, and phy principles underlying the construction of anæsth apparatus. For the rest there can be nothing praise. The authors are all experienced London an thetists, and, while their own views naturally rece prominence, they do give a fair review of other metho In the 38 chapters the whole field of clinical anæsth is covered, and that fact alone puts the book in a cl by itself.

Modern Treatment Yearbook 1949 (London: Medi *Press.* 1949. *Pp.* 338. 15*s.*).—This volume, edited by Cecil Wakeley, contains some fifty short articles on vari common conditions. They are divided about equally betwe medical and surgical subjects, and as in previous years written with an essentially practical outlook. The materi chosen is necessarily of varying importance, but the numero authors have obviously all approached their subject with th purpose of providing concise and helpful information, eve if much of it is not *particularly "modern."* This useful seri of low-priced handbooks would be even more useful, perhap if some way could be found of indexing the whole seri together, so that the practitioner could regard them as complete manual of treatment.

'GENATOSAN'

COLOURLESS TAR CREAM

('Genatosan' Dermatological Cream No. 19)

RMULA: w/w, Phenol 0.05%, Pyridine 125%, Toluene 0.10%, Naphthalene 0.50%, Cresol 0.05%, Carbazole 0.125%, Anthracene 05%, Phenanthrene 0.20%, Quinoline 025%, α-Picoline 0.025%, Xylene 0.05%, natosan' Base 98.8%.

CONTAINS the active principles of coal tar in an emulsified ointment base, but is free from the irritant and inert substances which are present in black tar.

The product is clean in use, will not cause irritation, and is particularly effective as an antipruritic.

Indicated for pruritus, prurigo, neurodermatitis, lichenification, infantile and chronic eczema, psoriasis and for all other conditions where tar therapy is of value.

Viscopaste and Ichthopaste Bandages

Viscopaste and Ichthopaste bandages are recommended as an alternative to elastic adhesive bandaging, in the treatment of chronic varicose and eczematous conditions and where the patient's skin is hyper-sensitive. Both bandages have non-fray edges and are thoroughly impregnated with zinc oxide gelatin paste of the Unna type. Ichthopaste contains, in addition, 2% Ichthyol.

Available in 6 yd. lengths by 3½" wide.

Descriptive literature may be obtained on request to the Medical Department of the Manufacturers.

VISCOPASTE & ICHTHOPASTE Bandages *are made in England by T. J. Smith & Nephew Ltd., Hull*

BRITAIN'S
STREPTOMYCIN

Glaxo Laboratories Ltd. recognise the responsibility placed upon them by the official announcement that their streptomycin products are generall available on prescription from November 1st, 1949. The manufacture **Streptomycin Glaxo** (calcium chloride complex) is today on a substantial and expanding scale. No increased demand can be met at presen however, for **Dihydrostreptomycin sulphate Glaxo,** the production of which remains limited for the time being.

The need for exceptional care in the domiciliary use of streptomycin w readily be appreciated. Informative literature is available to the medi profession on request.

Both products available in cartons of ten vials, each vial containing mate equivalent to 1 gram streptomycin base (1 mega unit) 70/- per carton
Less usual professional discount.

Economy

a the moment the Minister of Health has
ssfully defended the National Health Service
st arbitrary cuts that might have done it much
ge. But the pressure will continue—first on the
id that equally good value might be obtained
ess expenditure. and secondly on the ground
the country cannot at present afford a good
ce.

e there grounds for thinking that we are not
ng a pint out of the pint pot? If we are candid
nust surely admit that there are places where
eciable leaks may be suspected. For example, it
is a fair guess that a business consultant called
have a look at the rapid and expensive growth
he hospitals, and their high cost relative to the
ices of the general practitioner, would ask what
he relationship of the two, with reference to
hods of remuneration. On hearing that general
titioners are paid capitation fees but are at
rty to refer their patients to the hospitals for
nosis and treatment, he would observe that here
point which calls for inquiry. He might remark
if no change in the financial arrangements can
ontemplated, at least accurate information should
available as to what is happening, so that the
ess can be guided and controlled. Reference
atients to hospitals rose steeply after 1911, and
present financial arrangements are likely to
ourage the process to go further: and this shift
he centre of gravity towards the expensive hospital
specialist services is further stimulated by the
that it is to everyone's interest to press on
ards expansion. The consultants are naturally
for more sessions and for more registrars. Even
chief executive officer's remuneration is stepped
in accordance with the increasing number of beds
he group for which he is responsible. These and
ny other important arrangements have been settled
n the best of intentions—what is medically
rable, and what is fair as between employer and
loyed—but without any sufficient eye to their
ring on the growth of the hospital and specialist
ices. Exhortations from the Minister or from
regional boards, or even cuts in the estimates, are
r substitutes for incentives to economy, and are
ost wholly ineffective. The technical elements
so easily able to sway the layman, at almost any
el from hospital management committee to Parlia-
nt itself, that unless matters are arranged on a
tem of checks and balances within the system
re can be little hope of controlling the expansionist
dencies.

econdly, there is the larger question: "can the
ntry afford the present rate of expenditure on
dicine and the other social services?" We are being
rned by our American friends that the burden of taxation is throttling our industries and threatening our standard of living. We as a country have embarked on this programme, financed out of taxation, not because we think that it will pay in terms of productivity (though that may incidentally be so) but because we think it right to redistribute the national income in this way, and because it has become part of our conception of the social democratic State. It was accepted by the electorate in 1945 and is not now likely to be reversed whichever party wins the next election. But the revenue side of the budget is mainly sustained by the income-tax and various other forms of taxation, a large proportion of which is levied on industry: and if we have to rely on our industries to buy us our bread and meat and cotton from across the Atlantic we cannot pile any more burdens on to them. Therefore, runs the argument, expenditure on the social services, however desirable and right, must be checked. This line of thought is now dominant: it will be all that the Minister of Health can do to hold the present line, and further advances, on which many hopes had been set, must be eschewed for an indefinite future. Yet the fact remains that, strange to say, there are large sections of the population, by no means all of them with large incomes, who have money to spare for this and that, for anything from sweet rations and nylons to television sets and holidays abroad—not to speak of an expenditure on tobacco sufficient to provide the Exchequer with a revenue three times as great as the whole cost of the hospital services. Is it really true that a country which has money in its pockets for all these things cannot "afford" to bring its hospitals for the chronic sick up to date? Is it not perhaps rather the case that we have not yet found the right way of financing the social service, and that the mistake has lain in loading this expenditure on to the national budget while the latter remains largely dependent on taxation of industry for its resources? Ought not the cost of the social services to be considered, not in relation to the total national revenue as computed by the Chancellor of the Exchequer for his Budget, but against the far larger total national income? Should not means be devised for making the necessary cost of a healthy community as much a first charge on each man's earnings as is his expenditure on food and shelter?

It is easy to write "and means devised"; but they would of course imply a revolution in methods of taxation. It was perhaps of the ultimate necessity of some such change that Sir Stafford Cripps had a glimpse when he spoke of a special tax to finance the health service. Big changes in our fiscal system, not cuts in the social services, may be the right answer to our dilemma. It certainly seems worth reconsidering the possibility of redesigning the pattern of taxation so as to reduce the load of the social services on industry, and give expression to a truer scale of values, in which health and education come to the fore and cigarettes and television masts are pushed into the background. We can, one suspects, have a good health service if we want it badly enough. And if we tell the Americans that we prefer to have our health service—and to wear our togas till they are patched and patched again—what is that to them?

Too Much Vitamin A

NEARLY 25 years ago Japanese workers[1] noticed that the crude concentrates of vitamin A then obtainable were toxic when given experimentally in massive doses to animals. Later work, summarised by MOORE and WANG,[2] led to the recognition of skeletal fractures with intramuscular hæmorrhages as the characteristic lesions of an excessive intake of vitamin A in young rapidly growing rats, while older animals were often found to die suddenly from massive hæmorrhages in the viscera, without skeletal lesions. VEDDER and ROSENBERG[3] suggested that the lesions in rats resembled scurvy, while LIGHT and others[4] demonstrated that the syndrome involved a hypoprothrombinæmia, which could be corrected, without affecting the bone injuries,[5] by the administration of vitamin K.

The clinical observation of hypervitaminosis A, however, pre-dated its scientific discovery by several hundred years. Arctic explorers, at least since Elizabethan times, have recognised that the liver of the polar bear is poisonous, causing drowsiness, headache, vomiting, and peeling of the skin. The possibility that vitamin A might be the toxic agent was raised when RODAHL and MOORE[6] found that the liver usually contains about 20,000 I.U. per g., which means that the fresh tissues have nearly half the activity of good halibut-liver oil. The symptoms reported in explorers have not included the skeletal fractures or fatal hæmorrhages characteristic of experimental hypervitaminosis A, but their absence should not rule out vitamin A as the toxic factor in bear liver; the explorers presumably suffered from the acute effects of one large meal of liver, whereas the rats were given massive doses of vitamin A over long periods. RODAHL[7] has recently examined further specimens of liver from bears killed in north-east Greenland, and has found that the toxicity is associated with the vitamin-A fraction and not with the residual tissues after the extraction of the vitamin. The toxic fraction, moreover, becomes innocuous when its vitamin A is destroyed. He has also reported that the liver of an arctic fox, which the Eskimos believe to be poisonous, came close to bear's liver with 12,000 I.U. of vitamin A per g.; the edible livers of the snow hare and walrus contained much smaller amounts. In further investigations with vitamin A from other sources he has obtained more evidence of the resemblance between hypervitaminosis A and scurvy.[8] Thus both the clinical picture and the post-mortem findings in guineapigs given excess of vitamin A were very similar to those caused by a scorbutic diet, while in each condition the ascorbic-acid contents of the liver and blood-serum were much reduced. In a dog large doses of vitamin A for 57 days caused bleeding and swelling of the gums, with a reduction of the ascorbic-acid content of the blood from the original 0·7 mg. per 100 ml. to zero.

Since there can now be no doubt that in excess vitamin A is toxic, the possibility of inj intensive therapy has to be considered. In the toxic symptoms only arise when the daily dose least 1000 times the requirement for optimum gro one would expect, therefore, that man would tolerate doses greatly in excess of his physio requirements. In agreement with this view c experience has shown that very large doses of vitamin—up to at least 100,000 I.U. daily in or 40 times the accepted requirement—may be without any obvious ill effects. But absurdly high dosing in young children has caused toxic sym Thus TOOMEY and MORISSETTE[9] observed fail growth and skeletal abnormalities in a two-ye child whose misguided mother had administered less than 500,000 I.U. of vitamin A daily for th months, while DICKEY and BRADLEY[10] repo similar symptoms in a three-year-old child who received 400,000 I.U. daily for at least 18 mon It is significant that in the first of these cases mother's enthusiasm for vitamin-A therapy was discovered in the course of treatment, after preliminary diagnosis of scurvy had been made.

Western Union and Health

A BASIC idea behind Western Union is "convergi progress." Article 2 of the Treaty of Brussels, sig in March, 1948, between the United Kingdom, Fran Belgium, the Netherlands, and Luxembourg—and force for fifty years—states that "The High C tracting Parties will make every effort in comm both by direct consultation and in specialised agenci to promote the attainment of a higher standard living by their peoples and to develop on cor sponding lines the social and other related servi of their countries." Pursuant to this article, t five Powers have set up, under a Council of Minist and a Permanent Commission, a series of exp committees, of which one is an expert committee health. This committee has now held four meetin at intervals of about six months, in London, Pa Brussels, and Luxembourg, and will meet next The Hague in March, 1950.

Their first task was to study the subjects on whi progress towards "converging development" cou be made, and it at once became clear that there we wide gaps in the information mutually available the respective health services. To remedy th a system of exchanges was adopted and later appro by the Council of Ministers and the Permane Commission. These interchanges have already beg to operate, and by the end of the year some t doctors and administrators will have spent abo a week in each of the countries concerned to repo on the public-health administration in their respecti fields: the personal contacts thus made have alrea proved most valuable. Other subjects studied inclu a French proposal for a limited reciprocal recogniti of qualifications of doctors and other health worke and subcommittees of experts have reported on t standardisation of control of substances used for t treatment of venereal disease, on methods of analy of drinking-water and sewage effluents, and on t andards of purity required for foodstuffs. Joint bcommittees have been dealing with assistance nventions, including treatment at spas, and with habilitation: the latter is now dealt with by separate committee. The convention on social and edical assistance, which will shortly be signed, ovides that nationals of one of the four countries ho are normally resident in another country and e without sufficient resources shall benefit (with rtain exceptions) on an equality with the nationals the host country from the legal provisions for social d medical assistance: it thus does not apply to sitors. The scope and results will largely depend the administrative agreements on its application, hich have yet to be worked out.

Perhaps the question on which the greatest practical lvance has so far been made is that of simplification health control at seaports and particularly airports. he principle has been adopted of treating the five untries as one country for this purpose, which eans the abolition of all health controls for aircraft d passengers making flights within the five countries save in exceptional circumstances—and instituting e health control only for aircraft and passengers riving from outside: this sounds comparatively mple, but has involved much detailed work. The ritish Ministry of Health have already anticipated is on a limited scale in the so-called "Paris experi- ent," whereby passengers from Paris no longer ave to fill up the personal declaration of origin and ealth; so its inquiries into where the previous fourteen ghts have been spent will no longer be a source of bald comment.

Finally, there is the intricate question of the lation of the "get together" activities of Western nion to those of the Council of Europe and of the orld Health Organisation. Clearly there are some alth questions now being considered by Western nion which are susceptible of treatment on a uropean or world-wide scale: but it seems that eliminary consideration and action by the Western nion powers has been advantageous, and that mparative strangers should not be admitted too nickly to family conferences. As in other health atters, political considerations may provide stimulus but should be the servants and not the asters of sound technical progress.

Operations for Mitral Stenosis

IN operating on the mitral valve to relieve stenosis, o considerations have to be borne in mind. The rst is that with extreme stenosis of the valve the ft ventricle is small; at necropsy the posterior rface—i.e., the wall of the left ventricular inflow act—appears short and the coronary vessels tortuous ven though unaffected by atheroma.[1] The second onsideration is that artificial mitral regurgitation is oorly tolerated by experimental animals with normal earts, and extensive cutting of the anterior valve arries a high mortality-rate.[2 3]

Both Harken and his team[2] and Bailey[3] have ased their work on these facts; by approaching through the left auricular appendage they aim at relieving the stenosis without causing extensive regurgitation. Harken, whose various methods have already been reviewed,[4] has attempted to mobilise the rigid cusps by dividing the commissures (valvuloplasty); and he has also removed a segment of the posterior leaflet. Bailey, on the other hand, has confined himself to "commissurotomy," in which he extends the cut into the normal tissue surrounding the fibrotic area of the valve, believing that the raised auricular pressure will keep the artificial opening patent. Of 10 patients operated on by him, 7 died. Among the causes of failure were cerebral embolism on the sixth day after operation: an error in technique by cutting across the valve leaflet; postoperative obliteration by fibrin deposits of a small, calcified mitral orifice which did not permit of adequate cutting; postoperative intrapleural hæmorrhage attributed to the unnecessary use of heparin and incorrect fluid administration; and severe hæmorrhage due to friability of the auricular wall (which he has often encountered in mitral stenosis). To these dangers may be added two recorded by Harken—namely, tachycardia and dislocation of the heart from its natural position. Thus the risk of operating on the mitral valve is still great, even in the hands of experienced cardiac surgeons familiar with the precautionary measures. These include permanent electrocardiographic control and the administration of procaine drips to combat tachycardia and myocardial irritability. (This precaution is now held to be more efficacious when the procaine is injected intramurally in a 2% solution.[5]) The latest development is that Murray,[6] of Toronto, has succeeded in animal experiments, and in two patients with mitral stenosis, in removing one mitral leaflet and replacing it by an artificial leaflet consisting of a section of cephalic vein turned inside out and strengthened with palmaris-longus tendon.

Of the indirect surgical procedures, which are designed to relieve pulmonary symptoms due to mitral stenosis, two have already been mentioned in these columns.[7] One of these, designed to produce an artificial interauricular shunt, was inspired by the observation that mitral stenosis associated with a natural defect of this nature (Lutembacher's syndrome) may run a mild course, and that serious symptoms, such as pulmonary œdema and hæmoptysis, are then rare. Harken and his team[4] hold that an artificial auricular septal defect is indicated only when the cardiac output is normal and increases on exertion, and when stenosis and regurgitation coexist; otherwise the fall in left-auricle pressure may cause insufficient blood to reach the left ventricle through the stenosed valve. Another objection to this procedure is that the artificial defect may become obliterated and that embolism may ensue: however, work is in progress in the U.S.A. with the purpose of ensuring that the defect is both large enough and permanent. The second method, which is less hazardous, consists in creating an extracardiac venous shunt between the right dorsal-segmental inferior pulmonary vein and the nearby azygos vein by non-

Too Much Vitamin A

NEARLY 25 years ago Japanese workers[1] noticed that the crude concentrates of vitamin A then obtainable were toxic when given experimentally in massive doses to animals. Later work, summarised by MOORE and WANG,[2] led to the recognition of skeletal fractures with intramuscular hæmorrhages as the characteristic lesions of an excessive intake of vitamin A in young rapidly growing rats, while older animals were often found to die suddenly from massive hæmorrhages in the viscera, without skeletal lesions. VEDDER and ROSENBERG[3] suggested that the lesions in rats resembled scurvy, while LIGHT and others[4] demonstrated that the syndrome involved a hypoprothrombinæmia, which could be corrected, without affecting the bone injuries,[5] by the administration of vitamin K.

The clinical observation of hypervitaminosis A, however, pre-dated its scientific discovery by several hundred years. Arctic explorers, at least since Elizabethan times, have recognised that the liver of the polar bear is poisonous, causing drowsiness, headache, vomiting, and peeling of the skin. The possibility that vitamin A might be the toxic agent was raised when RODAHL and MOORE[6] found that the liver usually contains about 20,000 I.U. per g., which means that the fresh tissues have nearly half the activity of good halibut-liver oil. The symptoms reported in explorers have not included the skeletal fractures or fatal hæmorrhages characteristic of experimental hypervitaminosis A, but their absence should not rule out vitamin A as the toxic factor in bear liver; the explorers presumably suffered from the acute effects of one large meal of liver, whereas the rats were given massive doses of vitamin A over long periods. RODAHL[7] has recently examined further specimens of liver from bears killed in north-east Greenland, and has found that the toxicity is associated with the vitamin-A fraction and not with the residual tissues after the extraction of the vitamin. The toxic fraction, moreover, becomes innocuous when its vitamin A is destroyed. He has also reported that the liver of an arctic fox, which the Eskimos believe to be poisonous, came close to bear's liver with 12,000 I.U. of vitamin A per g.; the edible livers of the snow hare and walrus contained much smaller amounts. In further investigations with vitamin A from other sources he has obtained more evidence of the resemblance between hypervitaminosis A and scurvy.[8] Thus both the clinical picture and the post-mortem findings in guineapigs given excess of vitamin A were very similar to those caused by a scorbutic diet, while in each condition the ascorbic-acid contents of the liver and blood-serum were much reduced. In a dog large doses of vitamin A for 57 days caused bleeding and swelling of the gums, with a reduction of the ascorbic-acid content of the blood from the original 0·7 mg. per 100 ml. to zero.

Since there can now be no doubt that in excess vitamin A is toxic, the possibility of injury intensive therapy has to be considered. In the toxic symptoms only arise when the daily dose is least 1000 times the requirement for optimum g one would expect, therefore, that man would tolerate doses greatly in excess of his physiolog requirements. In agreement with this view clini experience has shown that very large doses of th vitamin—up to at least 100,000 I.U. daily in or 40 times the accepted requirement—may be tak without any obvious ill effects. But absurdly high o dosing in young children has caused toxic sympto Thus TOOMEY and MORISSETTE[9] observed failure growth and skeletal abnormalities in a two-year-o child whose misguided mother had administered less than 500,000 I.U. of vitamin A daily for th months, while DICKEY and BRADLEY[10] report similar symptoms in a three-year-old child who received 400,000 I.U. daily for at least 18 mont It is significant that in the first of these cases th mother's enthusiasm for vitamin-A therapy was on discovered in the course of treatment, after preliminary diagnosis of scurvy had been made.

Western Union and Health

A BASIC idea behind Western Union is "converg progress." Article 2 of the Treaty of Brussels, sign in March, 1948, between the United Kingdom, Fran Belgium, the Netherlands, and Luxembourg—and force for fifty years—states that "The High Co tracting Parties will make every effort in comm both by direct consultation and in specialised agenc to promote the attainment of a higher standard living by their peoples and to develop on corr sponding lines the social and other related servi of their countries." Pursuant to this article, five Powers have set up, under a Council of Minist and a Permanent Commission, a series of exp committees, of which one is an expert committee health. This committee has now held four meeti at intervals of about six months, in London, Pa Brussels, and Luxembourg, and will meet next The Hague in March, 1950.

Their first task was to study the subjects on which progress towards "converging development" cou be made, and it at once became clear that there we wide gaps in the information mutually available the respective health services. To remedy th a system of exchanges was adopted and later approv by the Council of Ministers and the Permane Commission. These interchanges have already beg to operate, and by the end of the year some doctors and administrators will have spent abo a week in each of the countries concerned to repor on the public-health administration in their res fields: the personal contacts thus made have already proved most valuable. Other subjects studied include a French proposal for a limited reciprocal recognition of qualifications of doctors and other health workers and subcommittees of experts have reported on th standardisation of control of substances used for treatment of venereal disease, on methods of anal of drinking-water and sewage effluents, and on

n America a similar dissatisfaction with traditional rapy has led to the search for new amœbicides. tely Anderson and others[1] have described the action two trivalent thioarsenite derivatives of carbarsone— dithiocarboxyl methyl derivative and the dithio-boxyl phenyl one. They claim that if the trivalent enic atom is masked by one of these thioarsenite ups its toxicity is diminished while its therapeutic ivity (as judged on infected rats and monkeys) nains unchanged. Chemical opinion in this country, vever, considers that these thioarsenite linkages are drolysed in solution and therefore will be loosened l more easily in the body; fundamentally the use these compounds is only a convenient way of giving valent carbarsone oxide, the active form to which inactive pentavalent carbarsone is converted in the dy. The Americans treated 82 patients with total ses of 3 0–4·2 g. by mouth in seven to ten days or 7·2 g. in ten to twenty-four days (either compound). ur months later, 74 of the patients were found to be ar of the amœbic infection, and the smaller dosage med to be as effective as the larger. Twelve of the tients vomited after the first one to three days' treatment; there were no other toxic reactions except reased bowel movement after the third to sixth day. ie two compounds were also found to be effective ainst infections with *Balantidium coli* (2 patients) it not against the other infections in which they were ied. On the face of it, these results seem promising. it since, from the chemical side, the new compounds not differ greatly from carbarsone inside the body, and ice carbarsone is generally recognised as being adequate as the main element of treatment, we should rhaps not draw any definite conclusions until several rther clinical reports have either confirmed or refuted is one.

A more interesting development concerns the new itibiotic, aureomycin. McVay and others[2] have ven this by mouth to 3 patients with amœbic dysentery divided doses of about 2 g. per day to a total of 19–22 g. he treatment caused the disappearance of *E. histolytica* om the stools and relieved symptoms, and the patients mained free from amœbæ and cysts for three weeks fterwards. No toxic effects were observed, apart from ausea for 48 hours in one patient. Here again it is too on to assess the value of the remedy, but the apparent sponse of this stubbornly resistant disease to an ntibiotic alone is a hopeful sign.

PARENTERAL PROTEIN IN INFANCY

SINCE their introduction ten years ago protein digests ave entered increasingly into the treatment of infants. Villiams and others[3] have lately published for the ledical Research Council's committee on the protein equirements of infants a report on 'Casydrol,' a British nzymic digest of casein. At the Children's Hospital, irmingham, they found that the intravenous infusion f casydrol is without danger, provided it is not given in reater concentration than 2·5%. They followed the tandard practice of always relieving any dehydration ith glucose and salt solutions and establishing a free low of urine before starting the maintenance infusion ontaining casydrol. They point out that since the odium in a continuous infusion of casydrol for a 10 lb. nfant may be equivalent to as much as 2 g. of sodium hloride per day, one must watch for signs of salt retention such as œdema; and they suggest that other reparations, such as the American 'Amigen,' which ontain about half as much salt as casydrol, are preferable because they can be more safely given in larger amounts than the conventional 1 g. per lb. body-weight per day which is the bare maintenance requirement of protein in infancy. They urge that casein hydrolysates should be given slowly, as by a drip, because of the risk of serious systemic reactions when they are given more rapidly, as by injection. Williams and her colleagues also indicate the desirability of improving nutrition by increasing the glucose content of parenteral solutions to 10%—a practice which is usually shunned because of the allegedly increased risk of venous thrombosis but which has been successfully adopted in America.[4 5]

Better results have been achieved with parenteral maintenance therapy in the last few years not only because of the introduction of protein digests but also because of the more accurate estimation of water and electrolyte requirements, the giving of optimal amounts of vitamins, and the routine prophylactic use of penicillin and sulphonamides. The Birmingham report concludes that the nutrition of very sick infants is benefited by the introduction of casydrol into their electrolyte-glucose intravenous solution, and that with such an addition infants will survive long periods of parenteral feeding.

NEW DEVICES AT THE LONDON

SOME antique practices in the handling of soiled linen persist in many of our hospitals. It is customary for nurses, before sending linen down to the laundry, to count and sort it in the ward, and to "sluice," or rinse out, badly soiled articles in the sluice-room—or even in the ward bathroom. The laundry-maids count the linen again, both before and after washing it, and the nurses count it once more when it gets back to the ward. The whole elaborate process is not only time-consuming but unhygienic and even at times dangerous. The London Hospital, a pioneer in the neglected art of leaving nurses free to nurse, has solved this problem. No linen-counting is done anywhere in the hospital. Each ward has its linen-trolleys—large tubular canvas sacks suspended open-mouthed on circular iron frames which run on castors. These frames are light, and can be easily wheeled to the bedside, where soiled bed-linen can be tucked uncounted into the sack. Filled sacks are taken from the frames, tied up, and dropped down a chute to the basement, where an electric trolley carries them to the laundry. They are sorted, washed, and returned uncounted to a central store; and from this store the ward sister indents daily for what she wants. Badly soiled linen is tied up separately and washed separately in the laundry. Thus linen sorting and counting, and the sluicing of soiled linen in the wards, as well as all the vexations of stocktaking day are avoided; and all the hospital linen is in constant circulation: no large stocks have to be kept in the wards, waiting to be used. A method of checking stock is necessary, of course. Every article is embroidered with the year of issue and a serial number; and when the sheets issued in a given year are to be checked, the sister at the central linen-store notes the numbers down as they pass through; over a period of three months an accurate report on the number circulating can always be made.

Various new measures have lately been taken at the London Hospital for the comfort of patients. Curtains on all-but-silent runners can now be drawn to form a cubicle round every bed; and while the nurses are glad to be spared screen-carrying, the patients rejoice in the added privacy. The only screens left are used to isolate patients who develop respiratory infections: they run on castors like the linen-trolleys and are covered in suture anastomosis with Blakemore's 'Vitallium' tube. Bland and Sweet,[8] the originators of this technique, have now reported their operative results in 5 patients, all of whom had frequent attacks of pulmonary œdema and hæmoptysis; in each of these patients pulmonary hypertension was associated with significant further rise of the pulmonary pressure on gentle exercise, and the left-auricle pressure was 400–500 ml. of water—i.e., 4–5 times the normal. Their hearts were not grossly enlarged. In 1 case, biopsy of the lung during operation revealed hæmosiderosis with thickening of the walls of the small arteries and the alveoli. Bland and Sweet believe that these cases belong to a group in which the patients eventually succumb not to cardiac but to pulmonary failure, though hypertrophy of the right ventricle usually develops: "They die before their time as far as their hearts are concerned." At operation, *as soon as the anastomoses were established* and the pulmonary clamp released, blood rushed with great force through the channel from the pulmonary into the azygos vein, and the pressure in the left auricle fell. Of the 5 patients, 4 did remarkably well; exercise tolerance improved and they remained free from pulmonary œdema and hæmoptysis for 12, 5, 4, and 2 months respectively. The 5th patient, a woman of twenty-five, died on the 11th day after operation. Before operation she had shown signs of active carditis, which was later confirmed at necropsy when a fresh antemortem clot was also found to have occluded the anastomosis; and Bland and Sweet point out that before operation smouldering carditis should be carefully sought. As to technique, they suggest that anastomosis without the intermediate vitallium tube may prove preferable. The sine-qua-non for this kind of escape-valve operation is a high pressure-gradient from the pulmonary to the systemic vein, as has been emphasised by Swan [9] who, apparently independent of Bland and Sweet, conceived the idea of the same kind of venous shunt, which he has performed in normal animals. Whether the shunt was accomplished by the tube method or by end-to-end suture, it remained patent only when a high pressure-gradient was introduced.

If further trials prove that the artificial channel remains unoccluded, the indirect approach may well be preferred by the clinician, whose main concern is to relieve dyspnœa, recurrent pulmonary œdema, and hæmoptysis. Shunt operations that bring about a flow of blood from the left auricle or pulmonary vein to the right auricle or systemic vein must inevitably inflict an increased load on the right heart; but so far there is no evidence that failure of the right heart ensues, and in Lutembacher's syndrome such failure does not usually develop until a late stage. With its great capacity and established hypertrophy, the right heart—unlike the left ventricle—is prepared to deal with an increased volume of blood, provided of course that the cavity is not grossly dilated and the myocardium is not damaged. Under certain conditions of stress the increased activity of such a hypertrophied right ventricle may flood the lung, the outlet side being partly blocked at the mitral valve.[8] It is therefore surprising that so far apparently no "vent" operation to relieve pulmonary hypertension has been carried out; it might seem that such procedure, consisting perhaps in creating an artificial incompetence of the pulmonary valve, would be technically easier than the "shunt" procedure. Certainly direct mitral-valve surgery is still a formidable undertaking, fraught with great technical difficulties and dangers; and the cardiac surgeon will always have to remember that even after the most brilliant technical achievement on the mitral ostium, the ultimate result rests with the myocardium of the left ventricle, which has become accustomed to receive and eject a reduced amount of blood.

Annotations

CHARGE FOR PRESCRIPTIONS

It is a little ironical that, sixteen months after the introduction of free medical care, insured persons should now be asked to pay for their medicines—for the first time since 1911. Unfortunately, though old-age pensioners are to be excused the new charge of "up to a shilling" for each prescription, there are others to whom it may mean the re-erection of a barrier, if a small one, in the way of medical treatment, and the charge should perhaps be remitted in the longer illnesses—e.g., after four weeks' incapacity. The prospect of paying several shillings for medicine may keep some people away from the doctor, but at least it is better that they should pay for drugs and dressings than for mere access to the surgery. Practical difficulties may arise over the collection of payment by rural doctors who do their own dispensing and sometimes send the medicine to the patient by the local bus; and the Prime Minister did not say whether hospital dispensaries will make a charge—as they presumably should if patients are not to seek repeat medicines in outpatients.

To those who are anxious to see the National Health Service create better conditions of practice it has been galling to watch it fostering rather than restraining the bottle-of-medicine habit. The rise in the average annual pharmaceutical cost per person at risk from 4s. 9d. under National Health Insurance to just under 8s. last February [1] was partly due to higher dispensing fees, but also partly to a larger number of prescriptions per person: in Middlesex, for example, this rose from 1·93 in the last six months of 1947 to 2·47 in the last six months of 1948.[2] As everyone knows, a great many of these prescriptions have been for household remedies for which the doctor should never have been bothered at all, and there is reason to think that this abuse, so far from diminishing has lately grown. In so far as the new arrangement helps to "reduce excessive, and in some cases unnecessary, resort to doctors and chemists" it will be welcomed by the profession.

TREATMENT OF AMŒBIASIS

In Britain during the later years of the war a good deal of dissatisfaction was expressed over the results of treating chronic amœbic dysentery with any of the standard remedies. Most of the authorities favoured emetine bismuth iodide by mouth, reinforced with arsenicals (e.g., carbarsone), bismuth, or quinoline compounds (chiniofon, diodoquin) according to taste. Some of the failures were probably due to the type of cases treated—soldiers with many previous relapses and secondary bacterial invasion in the large intestine. These were often much benefited by courses of penicillin and succinyl sulphathiazole which suppressed the bacteria and cleared the way for emetine to work on the amœbæ.

subjective sensation, would work out in practice. tient suffering from shock or full of first-aid morphine ld probably be an unreliable witness on the finer cts of pain sensation. It might, however, be argued information on burn depth would not be required the patient had become fit for an operation (if was indicated), by which time he would be fit to erate in skin-sensitivity tests. The method (and rs) clearly merits an extensive clinical test, and Birmingham Accident Hospital will no doubt ide one.

PSYCHIATRIST LOOKS AT TUBERCULOSIS

. Wittkower[1] has spent $2^{1}/_{2}$ years in the psychoal study of tuberculous patients—a project undern under the auspices of the National Association for Prevention of Tuberculosis. By interviewing 785 nts, drawn from all social and economic grades and all age-groups, in sanatoria (good, bad, and ferent), at dispensaries, in their homes, at their s of work, and in village settlements, he has cond to review a very fair cross-section of the tuberculous munity. Each patient was interviewed for at least hours, during which time he was skilfully drawn out veal—not only to the psychiatrist, but very often s own startled self—his reactions towards his illness all its implications, his previous personality, and his situation before the onset of his disease.

ere are only three chapters. In the first Wittkower ribes the behaviour of tired and toxic patients re they go sick, how they may respond at the ent of diagnosis, and how they may react thenceard towards their illness. At first reading this ars to consist of little but spotlit glimpses of the ous; but when, in the second chapter these familiar ties of reaction are correlated with their determining hological factors they are revealed in a very different Wittkower admits that he had expected to unter a somatopsychic rather than a psychosomatic lem; but as his work progressed his interest shifted the rather obvious effects of suffering from tubercuon the patient's psychology to the more subtle ts of the patient's psychology on the incidence and se of his disease. In his last (and most thoughtoking) chapter he explores the possible connexion een a person's mental make-up and his predision to tuberculosis. The premorbid personalities d in 300 patients so investigated fall roughly into main groups: overtly insecure types (39%), llious types (12%), self-drivers (29%), and conflictssed types (13%). These are so graphically and quially described as to be easily recognisable; but identification with standard personality types, as ribed by Kretschmer, Jung, and other workers, is emely difficult. The reader, moreover, may well "Does the whole of humanity fall within these categories? (And if so, which am I?) And if not, would Dr. Wittkower describe those remaining s who apparently are immune from tuberculosis?" e finds that the outstanding common feature the premorbid personality is an inordinate need rt or concealed) for affection, coupled with cons over dependence. Again it may be asked, what extent is this maladjustment the lot of anity? Is it as rare (4 per 1000 population) as monary tuberculosis? Or is it so common that the xistence of tuberculosis might be accidental?" It ld be quite impossible to submit comparable groups normal healthy individuals to a similar inquisition ut their private lives; "normal" controls are therefore out of the question. But it would have been interesting to compare and contrast these findings in the tuberculous with those in patients suffering from other chronic diseases. There is no indication that the premorbid condition Wittkower describes is specific for the tuberculous. It may indeed be the common denominator of all illness; and, given this premorbid condition and a breakdown in psychological defences, a man might fall ill with whatever disease was handiest: one for which the stage was already set by heredity, lack of resistance, and infective organisms.

The statement that the prevalent mood among the tuberculous is that of anxiety and depression will come as a shock to many. Logically, of course, the situation created by a disease of unknown duration and uncertain prognosis should produce both anxiety and depression; but much the same situation confronted troops going into battle and Londoners facing a blitz, and conceivably their mood might have proved on psychiatric examination to be the same; but they did not show it. In terms of acceptance and rejection, the vast majority of Wittkower's patients appear to be rejecting the situation. Of the 24% who showed slight concern, only a small proportion "resigned themselves to the inevitable"; and "resignation" surely suggests a passive packing-up rather than an active acceptance? He admits that his book is incomplete: pressure of time did not allow full analysis of much of his voluminous data. We leave the patients, so to speak, still incapacitated by their disease and still uncertain of its outcome, and we wonder what happens to the psychology of those millions who arrest their disease and return to more or less normal life, and of those who, five or more years later, have almost forgotten they had ever been in a sanatorium. What has the tubercle bacillus done for them?

[1] Psychiatrist Looks at Tuberculosis. By ERIC WITTKOWER, M.D., psychiatrist to the skin department, Saint Bartholomew's Hospital, London. London: National Association for the Prevention of Tuberculosis. 1949. Pp. 143. 12s. 6d.

COMMITTEE ON PRESCRIBING

THE Central and Scottish Health Services Councils, constituted under the National Health Service Acts, have jointly appointed a committee "to consider and report from time to time whether it is desirable and practicable to restrict or to discourage the prescribing by practitioners giving general medical services under the National Health Service Acts of 1946 and 1947 of (i) drugs and medicines of doubtful value or of unethical character; (ii) unnecessarily expensive brands of standard drugs." The members are:

Miss Janet Aitken, F.R.C.P.; Prof. Stanley Alstead, F.R.C.P.; Dr. J. A. Brown; Sir Henry Cohen, F.R.C.P.; Prof. E. C. Dodds, F.R.C.P., F.R.S.; Prof. D. M. Dunlop, F.R.C.P.; Dr. F. Gray; Dr. P. Hamill, F.R.C.P.; Mr. J. C. Hanbury, F.R.I.C.; Dr. G. MacFeat; Prof. Chassar Moir, F.R.C.O.G.; Dr. A. Smith Pool; Mr. J. H. Ramsay, PH.C.; Dr. W. D. D. Small, F.R.C.P.E.; Sir Henry Souttar, F.R.C.S.; Mr. D. E. Sparshott, M.P.S.; Dr. J. G. Thwaites; and Alderman W. J. Tristram, M.P.S.

At its first meeting the committee elected Sir Henry Cohen as chairman and Professor Dunlop as vice-chairman.

This new body is additional to the joint committee[1] which the Minister of Health asked the Central Health Services Councils to set up with a view to deciding, for the purpose of prescriptions, what substances are medicines and what are foods. We understand that the latter committee is already sitting.

Dr. C. O. HAWTHORNE, a former chairman of the representative body of the British Medical Association, died at his home in Hove on Oct. 24.

The next session of the General Medical Council will open on Tuesday, Nov. 22, at 2 P.M., when Sir Herbert Eason, the president, will deliver an address.

---

[1] See *Lancet*, 1948, ii, 1020.

glass-clear plastic which allows the patient to see everything going on around him and merely intercepts his droplets. Bedside commodes are now in regular use; the light chromium pan, with a fitting lid, is set beneath an ordinary lavatory seat in a wheel-chair. The pan, and the rack which carries it, can be removed, and the seat will then fit over the pan of the ward water-closet. The nurses find that patients generally prefer being taken to the lavatory to using the commode at the bedside; and if they are well enough to get into the chair they are usually fit to be wheeled to the closet.

Each patient has his own thermometer in a test-tube hung in a clip at the head of his bed. His wireless headphones plug into a switch by means of which he can select his programme. For those who are not up to using headphones, 'Pillotones' are provided. These are about as big as a Yorkshire parkin, and lie comfortably under the pillow delivering music, vaudeville, or Women's Hour softly into the sufferer's ear. The wards are newly painted in a gentle oyster shade known locally as "putty B" or "Matron's grey"; and the green curtains of the cubicles look well against it.

The empty-bed puzzle has also been very largely solved. The difficulty has always been that, as every chief has his own beds, a gynæcological case can never be put into an E.N.T. bed, or a patient with asthma into the bed of a neurologist. And as every houseman guards his chief's beds like Cerberus, there are apt to be empty beds in inconvenient parts of the hospital. At the London every ward has a side-room with a single bed in it which nobody can fill but the matron or the house-governor. If a patient needs to be admitted to a ward which is already full, one of these officers does a little juggling. A patient due to go out is moved into the side ward for a day or two, and the newcomer gets his place. These side wards mean that there are always 10 unallotted beds in the hospital which cannot be claimed by housemen on behalf of their chiefs; and by the judicious use of these the empty-bed rate has been reduced from 21%, before the war, to 5%.

Patients' relatives make their telephone inquiries direct to the ward, and receive a much fuller account than is possible when inquiries are answered from the gate. The task of dealing with these calls is among the duties allotted to the newly appointed ward clerks.

MOTH-BALL ANÆMIA

IN England the moth-ball is gradually disappearing, its place being taken by D.D.T. in various forms. But in the United States the traditional moth-balls are still in current use, at least among the negro population. Now moth-balls are shiny glittering objects, just the kind of thing that any child of 2 years or so would want to put into its mouth, and the piccaninnies of Detroit seem to like sucking them as well. For Zuelzer and Apt[1] report four cases of acute hæmolytic anæmia in negro children of this age, all due to sucking moth-balls; and surely the surprising part of their paper is that they could not find any previous reports of such cases. The explanation may be that those who treated the patients never thought of asking about moth-balls; Zuelzer and Apt had always to probe for the history—for instance, in one of their cases a neighbour had seen the child sucking a moth-ball.

Moth-balls are composed of pure naphthalene, and this chemical is presumably responsible for the syndrome that comes on 1 to 4 days after ingestion. The child looks listless and ill, may vomit and have diarrhœa, and goes pale but not icteric. Quite soon the urine turns a "port-wine" colour and tests reveal hæmoglobin in it; no porphyrins are found. The free hæmoglobin in the plasma is considerably increased. The blood smear shows fragmented red cells, and in one patient (Heinz) bodies were found inside the red cells. T severe anæmia, with hæmoglobin levels reduced to 5 per 100 ml. or less; there is a well-marked leuc and many nucleated red cells appear. The red show spherocytosis and increased fragility in solutions. All tests for abnormal agglutinins hæmolysins are negative. Reticulocytes appear tually and their increase heralds the recovery. All this is typical of the picture of an acute anæmia due to any cause. Zuelzer and Apt could no other cause than naphthalene poisoning in young patients. But they decided to put the the test by feeding known amounts of flake to dogs. The clinical picture seen in the children accurately reproduced in the dogs; the of erythrocytes and the Heinz bodies were also when reticulocytosis occurred the number of bodies declined and recovery set in.

All four children were treated with blood- and recovered without incident. It is clear that if history of sucking moth-balls had not been the diagnosis might have been Lederer's anæmia; the presence of acute anæmia and spherocytosis might tempted some clinician to diagnose an acute phase of hereditary spherocytosis and to recommend splenectomy. Splenectomy has no place in the treatment of such cases; they will recover if tided over the acute phase by blood-transfusion. Not much moth-ball anæmia is likely to be seen in this country, but the report will remind us how well worth while it is to take a thorough history.

ESTIMATING THE DEPTH OF BURNS

IN fresh burns it is often impossible to tell by eye whether the skin has been totally or only partially destroyed. Yet the information may be important because excision and grafting of a burn will save much time if the skin is totally destroyed; whereas it is meddlesome, if not positively harmful, to excise and graft a burn which still contains living epithelium and will heal rapidly by itself. A few days must usually elapse before the depth of burning can be estimated clinically, and meanwhile infection may have occurred to jeopardise delayed surgical enterprises. Various attempts have been made to devise immediate tests for the degree of skin destruction. Dingwall[1] has suggested intravenous fluorescein and examination of the burn under ultraviolet light for fluorescence. Patey and Scarff[2] used Van Geison's stain (picrofuchsin) on fresh burns and found that areas of partial skin loss stained pink whereas total skin destruction resulted in yellow coloration.

The latest of such tests has been devised by Bull and Lennard-Jones,[3] at the Birmingham Accident Hospital. Following the knowledge that burned surfaces became partly or completely anæsthetic, they investigated the sensitivity of experimental burns produced on themselves. Pain was found to be the most reliable of the skin sensations and was evoked by using weighted needles. Partial-thickness burns showed diminished pain sensibility, whereas full-thickness burns were completely or almost completely anæsthetic with a surrounding zone of hyperæsthesia. Using needles weighted to 3 or 6 grammes with blobs of solder, they investigated actual burns in six patients and confirmed the experimental results. Biopsies and clinical progress, both in the experiments and in the cases, confirmed the depth of burning. Without disparaging the careful and valuable observations of the Birmingham workers, one may wonder how a test of this kind, which depends invalid as being contrary to section 51 (23A) of the monwealth constitution; but it was severable ı the rest of the Act.

r. Justice McTiernan, dissenting from "conscription," that the material aid given by a scheme to cater human needs was commonly described by the word nefit." Applied in this sense, the word signified ecuniary aid, service, attendance, or commodity e available for human beings under social-welfare ocial-security legislation. State law commanding ıctor to sign a prescription or to date it would not ıge the doctor in the service of the State. It would be a form of conscription. This section did not ide for any form of civil conscription. The Act not by any form of law call on any doctor to serve Commonwealth. No doctor was any less a private titioner than he was before the Act was passed. loctor was legally free to decline to write any cription under section 7A.

Public Health

PERIENCE WITH B.C.G. VACCINATION OF STUDENT NURSES

F. Harwood Stevenson
M.D. Lond., M.R C.P.
NSULTING PHYSICIAN, ROYAL NATIONAL ORTHOPÆDIC HOSPITAL

HIS is an estimate of the Mantoux state of the nurses he country branch of the Royal National Orthopædic pital over the last three years, and a report on the G. vaccination of Mantoux-negative student nurses at same hospital in the past year.

MANTOUX STATE ON ENTRY

he total entry in the three years was 157. Of these, were Mantoux-negative and 85 Mantoux-positive on val. The figures for the third year (37 Mantoux-ative and 17 Mantoux-positive) contain a much ler proportion of Mantoux-negative reactions than se obtained in the earlier two years (35 Mantoux-ative and 68 Mantoux-positive).

or most of the period under review Mantoux tests e done with Old Tuberculin in dilutions of 1/10,000, wed if necessary by 1/1000. During the last six iths the nurses negative to 1/1000 were tested with 0. Of the 20 new entrants in this period 12 were ative to 1/100, 6 were positive to 1/10,000 or 1/1000, only 2 who were negative to these dilutions were itive to 1/100.

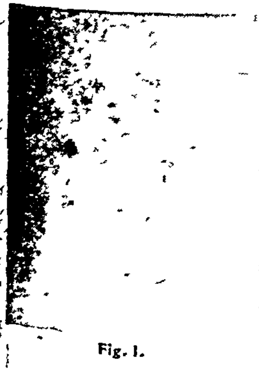

Fig. 1.

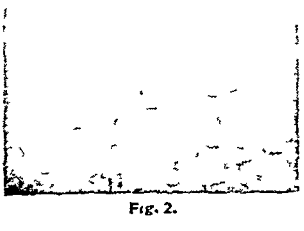

Fig. 2.

1—Papules developing after intradermal multipuncture of B.C G. (Actual size.)

2—Lesion obtained by intradermal injection of B.C.G., in a rurse from Scandmavia. (Actual size.)

During the first four months a commercial ready-diluted Old Tuberculin was used for the tests. This was supposed to be reliable for three months, but one nurse whose chest radiogram showed a healed primary lesion reacted negatively to 1/1000; so a change was made to freshly made dilutions. The same nurse when retested was then positive to 1/10,000.

At the country branch there are about 100 cases of orthopædic tuberculosis. Open pulmonary cases are not taken or kept, however, and it is believed that the risk of contracting tuberculosis is no greater here than in normal life. This is borne out by the fact that there were, during the two years before B.C.G. was used, only 2 cases of Mantoux conversion in addition to the spurious one already mentioned. Each nurse had her chest radiographed, and the tests were repeated on all the Mantoux-negative student nurses at six-month intervals from entry.

A high proportion, therefore, of the girls beginning their nursing training at this hospital were Mantoux-negative and support was obtained for the belief that the risk from contact with our cases was minimal. Most of these girls start at Stanmore at about 17 years of age and go on to their general training after two years. It therefore became apparent that their time here was a useful period in which they might be converted to Mantoux-positive before meeting the probably greater risks of a general hospital.

B.C.G. VACCINATION

From October, 1948, B.C.G. vaccination was offered to the student nurses. Approval was obtained from their parents, and only one offer was refused.

Technique

Since B.C.G. vaccination was a new departure in British hospitals, it was thought wise to use the method least likely to give any untoward effects. Intradermal multipuncture was therefore chosen. The vaccine was spread on the skin of the upper arm after cleansing with ether. Forty small punctures were then made with a Hagedorn needle "on the flat."

There were no glandular enlargements, painful or otherwise, and in no case did any weeping lesion develop. All that happened was that in some cases various numbers of small papules about 1–2 mm. in diameter became visible in 10–30 days and disappeared in about the same time. Fig. 1 shows the papules obtained by this method, and fig. 2 a small single lesion obtained by intradermal injection in a nurse who came to England from Scandinavia shortly after receiving B.C.G.

Results

The following are the results so far obtained:

Nurses inoculated		26
Previous Mantoux state	Neg. to 1/1000	17
	Neg. to 1/100	9
Of the 26 inoculated—		
Papules were seen in		16
Papules were not seen in (one nurse was inoculated twice)		11

Of the 16 with papules, 15 were converted: 1 to 1/10,000, 1 to 1/1000, and 13 to 1/100.

Of the 11 without papules, 4 were converted: 1 to 1/1000 and 3 to 1/100; 2 other students gave up nursing and could not be tested.

The first five inoculations were made with B.C.G. 0·5 mg. per ml. Of the student nurses so inoculated, 4 developed papules and were converted. The 1 without papules remained Mantoux-negative to 1/100. The other 21 inoculations were made with B.C.G. 10 mg. per ml., as recommended by Dr. Wassen for the multipuncture method.

Thus the total number of conversions in 26 inoculated nurses was 19; 2 could not be tested; and 5 definitely remained negative.

PHARMACEUTICAL BENEFITS IN AUSTRALIA

Act Declared Invalid

FROM AN AUSTRALIAN CORRESPONDENT

By a four to two majority, the judges comprising the full high court of the Commonwealth of Australia have declared the Pharmaceutical Benefits Act to be invalid. The judgment was announced on Oct. 8.

Sir John Latham (the chief justice), Mr. Justice Rich, Mr. Justice Williams and Mr. Justice Webb held that section 7A of the Act amounted to a form of civil conscription. Mr. Justice Dixon and Mr. Justice McTiernan, dissenting, held that the Act was valid. The Chief Justice and Mr. Justice Williams also held that the invalidity of section 7A did not affect other provisions of the Act; if it were struck out, they said, the Act would work as a completely voluntary scheme. Section 7A prescribes that a medical practitioner should not write prescriptions for medicines in the formulary except on a prescription form supplied by the Commonwealth.

The defendants—the Commonwealth government, the Commonwealth director of health (Dr. A. J. Metcalfe), and the minister for health (Senator McKenna)—had demurred to a statement of claim by the British Medical Association and six New South Wales doctors. The defendants contended that the Act and regulations were within the Commonwealth parliament's powers.

The *Pharmaceutical Benefits Act was passed in 1944.* It was challenged and declared invalid in 1945. The next year, section 51 of the constitution was amended to give the Commonwealth power to provide social *services, including medical benefits, but not so as to* authorise any form of civil conscription. The Commonwealth government also relied on section 51, which gives it power to make laws in respect to "matters *incidental to the execution of any powers vested by the* constitution."

The B.M.A. claimed that the Act, and regulations made under it, went beyond the powers conferred by the *1946 constitutional amendment, and that they involved* a form of civil conscription of doctors; and that doctors would be hindered in the proper treatment of their patients by the requirements of the Act. It claimed *that the Act was invalid, or that seven sections and* twelve regulations were invalid.

CIVIL CONSCRIPTION

The Chief Justice said that the power granted to the Commonwealth government in 1946 under section 51 of the constitution did not entitle the government to make laws on pharmaceutical benefits and medical services, but only to provide such benefits and services. A power to make laws on medical services could be held to authorise a law for the complete control of medical services, and would *enable the government to control* medical practice completely. Similarly, a power to make laws on pharmaceutical benefits could authorise a law for the complete control of pharmaceutical chemists' business. "The object of conferring on parliament the power of providing pharmaceutical benefits was to provide these benefits under a scheme which would leave anyone at liberty to take part or stand aside, whether as doctor, chemist, or patient." The Chief Justice concluded that section 7A imposed a form of civil conscription and was *invalid, but this did not* affect the validity of any other provisions of the Act.

Mr. Justice Rich, agreeing with the judgment of "civil conscription," said that the original Pharmaceutical Benefits Act *was found invalid by a majority* of the high court *because it was considered* that power of appropriation of money under section 81 of constitution did not extend to payments for allowance, child endowment, and widows' since *social services were limited by* section 51 to invalid and old-age pensions. The addition to constitution in 1946 allowed for "the provision maternity allowances, widows' pensions, child ments, *unemployment, pharmaceutical,* sickness, hospital benefits, medical and dental services (but so as to authorise any form of civil conscription), ber to students, and family allowances." Mr. Justice *held that these services were to be provided* by Commonwealth and not by any State or other. The phrase "civil conscription" was, he said, thing of a novelty; military conscription and indu *conscription were a familiar combination. The* mentary draftsman had apparently shied at the simplicity of the word "compulsion," but, he thou that the phrase meant "compulsion in connexion w *medical and dental services." The crucial* questi was whether section 7A imposed civil conscription thus interpreted. Admittedly no-one was compell to adopt the profession of medicine; but, if he did *he was affected in his freedom of practice* and in h means of living unless he subscribed to the schem whereby he was subject to control as to the form treatment and the drugs he might prescribe. For th *general practitioner, non-compliance meant* loss practice. The use of a particular prescription was mere automatic action. It was the result of the prac tioner's examination, diagnosis, and choice of the trea *ment which his knowledge and skill dictated;* it the culmination of the medical service rendered by practitioner to the patient. This might perhaps be compulsion in the sense in which the word was u *in connexion with military service,* but it was a form civil conscription.

ANALOGIES

Mr. Justice Williams, *also agreeing* with the "ci conscription" judgment, said that it would no dou be a form of industrial conscription to compel people law to work in industries, whether industries w *carried on by the Common*wealth, or by the States their authorities, or by private individuals. It wou be equally a form of civil conscription of medical or de services to compel medical practitioners *to carry on* th *professions in particular* localities. A medical practiti was compelled to render that service in the cour rendering a contractual service to his patient, but it a service which formed no part of an implied contr for services created by a patient seeking the advice a treatment of a medical practitioner, and the practition examining the patient with a view to giving him and treatment.

Mr. Justice Webb, agreeing on the "conscr judgment, said that, when parliament came be patient and doctor and made lawful continuance of relationship as such dependent *on a condition,* en able by fine, that the doctor should render the a special service unless that service was waived by patient, it created a situation which amounted form of civil conscription. This civil conscription be avoided without any *breach of the law to the* e that the doctor vacated the field of medicine, w however, would involve in many, if not most, ca considerable loss of *practice* and income. But it was civil conscription. Military conscription would cease *to be such because those liable to* fight migh avoid it by a change of occupation. To amount civil conscription it was not necessary that the servi should be a full-time service, or should be rendered a member of a corps created for that purpose. Section 7

Disabilities

41. MANIC-DEPRESSIVE PSYCHOSIS

AM what Harley Street calls a manic-depressive, and ave been told, in that street, that I am a pronounced e. My malady did not establish itself until after I rried at the age of 37—in other words, until after my ains of living were inevitably multiplied, as for a man longer concerned only to keep going himself. But ad earlier noted signs of something weak in me: the efest being that, if I opened some hard book to read, h as Butler's *Analogy*, after twenty minutes or so I s as one dragged down into sleep. Then one dark ht, as I was walking on the beach, I became aware t the right side of my forehead felt as, in winter, a mb finger does. Standing still, I struck that side h a clenched fist, and my thought was that if what I t as an obstruction there to the circulation of the od should break down I could make something of life: terwise I was doomed to mediocrity.

I was then 18 or 19: I am now 73, and my life-course nearly 40 years has been a succession of alternate iods, each some 4½ months long, of unusual intellec- al activity and of overpowering lassitude: not such edness as follows an excess of physical or intellectual rtion, which with rest passes off, but a poison-tired- ss. The periods might almost have been measured by ate, one of the fabled Three, with a watch in her hand. ave become used to thinking of them as "up-times" d "down-times," and it will help me if I may use se terms.

For 40 years, then, I have lost half of each year for at can be called work; but during the up-times, en I always feel gorgeously well, nothing seems to tire e, and it is easy to do a double day's work, I have ked so hard that my output (I am a writer) compares t unfavourably with that of those who have kept at rk all the year. Just as I have been able to make arrears of my official work in the up-times, so have been able to make it up afterwards with my friends. I need not take your silences amiss," one lady once idly said, "you just *have* to hibernate.") I write both se and prose, lyrical poetry and literary criticism. y it not be that, had I not been a manic-depressive, hould have written no poetry? It has been thought at the urge to write poetry proceeds from a condition some degree pathological. If that be so, and if a man e had pleasure and joy in writing poems he would not ve written were he not pathologically conditioned, should not regard himself as having been compensated?

Born of scholarly parents, and since associated in ship and friendship with scholars, I have tried to come a scholar myself; and I still persist in the tempt, though nearly 40 years ago the hopelessness of all was forcibly brought home to me. I had spent much the preceding up-time teaching myself Sanskrit: ading the prose parts of the *Hitopadesa*. Then followed down-time, when perforce I laid that volume of fables ide, and by the time of recovery I had forgotten almost ery word of the language. It has been the same with many attempts to become a Persian scholar: I get each down-time all I have taught myself: so at I must say, jestingly, that all the Persian that abides ith me is *zulf-i-pareshan*—"dishevelled locks."

My disability must be regarded as a slight one compared ith most others; and as one, at least in my case, not eleterious to general health. In my 70s I still mb the Wensleydale hills with no more effort than I lt when I was 20. As a compensation for the down-times, experience a fire and exultation in the up. But I have ad to get through the times of depression, and the hought of each one as lying ahead has been a strong pur to me (perhaps too strong) to make a good use of my activities. For when I can no longer work I thus have something to remember as accomplished, to help counteract the feeling of being guilty of some crime for which I am wanted by the police, a feeling I have always had to contend with.

Before I pass to the palliatives, I must dwell on what I have had to palliate. The worst trouble I have just had to grin and endure. This is the craving for more sleep in the down-times, which I feel on waking every morning, and after every short sleep during the daylight hours. Mercifully, getting up and doing what must be done usually reduces the craving appreciably, and I normally feel much less heavy and tired during the last hour or two of each day. Often I have only got through getting up, washing, dressing, and having my breakfast by knowing that I should be free to go to sleep again immediately after the meal, either in my own room or seated on a bench in a park. I have discovered no palliative for that part of the trouble: and it has been on waking (only then) that I have often thought it would be sweet and pleasant if, as I turned a street corner, the bullet of an assassin, meant for another head, entered mine. In down-times, feeling a numbness in my head, as if it had nothing but a lump of damp sawdust inside, I have thought it would be pleasant, for the mere change of sensation, to jab a needle through my skull.

One day I made a discovery. I had waked with a craving for more sleep, and was proposing to fall asleep during the day over a book, when I was summoned to be ready, having packed for a lengthy stay in a Himalayan hill-station, to conduct two schoolboys late that day to a station en route, to continue the journey myself, and in the hill-station to find and rent a house for the party. An instinct led me to pass through my mind as much of Shelley's *Ode to the West Wind* as constant reading had taught me. I found I knew it all except the beginning of the second verse—some seventy lines. These I passed through my mind all day, never stopping: in the train I even recalled the missing lines by concentrating on the rhymes in those that I knew. In this way I prevented my mind being preyed upon by thoughts of the police.

That led me to another discovery, but not until long years had passed. This was that, during a down-time, when I do no work and have consequently a mind empty except for fear, I can memorise verse more easily than at any other time. So in the last down-time I started at the beginning to memorise Racine (*Bérénice and Phèdre*); the time before it was Virgil, Dante the time before that, and on another occasion book XII of *Paradise Lost*.

The lassitude of the down-times has been so heavy, so paralysing, that I have had to shape my days so that I could do all my work in the up-times. And then, too, I go for the long walks that are my form of exercise. During the down-times any intellectual activity is so far beyond the power of my brain to perform that it is only sensible not to think at all, to avoid as far as possible all intercourse with others, write no letters, and fill in the many hours with the reading of endless books. Thanks to there being eight volumes of them and to the print being small, I got comfortably through most of one down-time with Greville's *Memoirs*, and through another with Carlyle's *Frederick the Great*, also in eight volumes. Long years afterwards my wife, poor soul, said: "How I got to hate Greville's *Memoirs*!"

There are always compensations, let a man but see them as such, and seek them. I have sought compensations (I mean, something to succeed in) in many directions. What stands out is this: since I realised so early in my working-life that I should live under a heavy handicap, I put away the desire to earn my living as a professional writer. I always had, until retiring age, a salaried post; and consequently I never had to write pot-boilers. I have been free to write when and what

Conclusions

(1) *The multipuncture method with a flat Hagedorn* needle produced no significant troublesome lesions.

(2) The conversion-rate of 19 out of 24 followed up left something to be desired, and the slightly greater risk of a local lesion with intradermal injection would probably be worth taking to improve the conversion-rate.

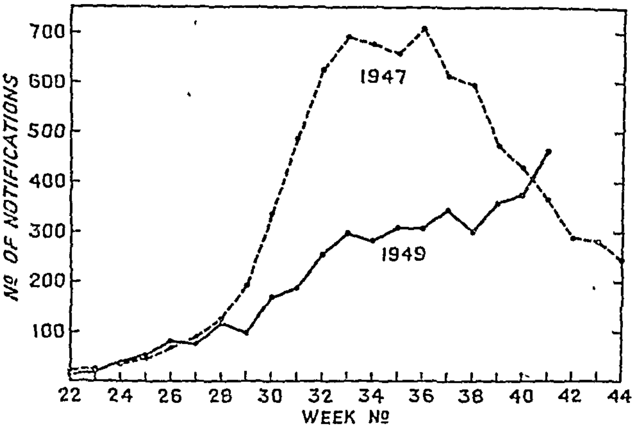
(3) The conversion-rate, in these small numbers of cases, was *as high with B.C.G. 0·5 mg. per ml. as with* 10 mg. per ml.

(4) As might be expected, the development of visible papules increased the chance of conversion, though they were not essential for success.

I am extremely grateful to Dr. A. Wassen, of Gothenburg, and to Professor Wallgren, who introduced me to him. On *numerous occasions in the last year supplies of vaccine have* been sent to England by air from Dr. Wassen's laboratory—a most generous gift. My thanks are also due to Dr. C. H. Lack, pathologist to the hospital, for most of the Mantoux tests, and to Sister Pursall, who has been most helpful in the considerable routine involved.

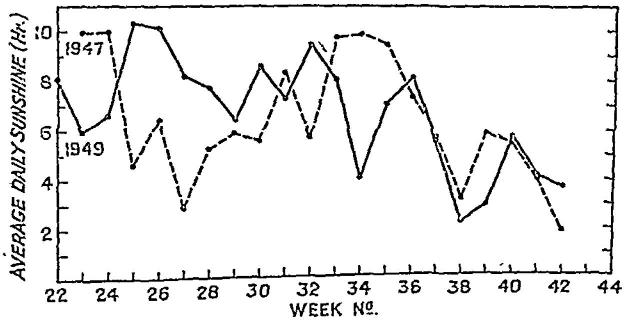
Poliomyelitis

In the week ended Oct. 15 notifications were: poliomyelitis 418 (340), polioencephalitis 45 (34). Figures for the previous week are shown in parentheses. This is a *substantial rise, and it is clear that the curve is following* a different trend from that of 1947. Multiple cases were reported from the following counties:



London 68 (53), Bedford 7 (5), Berkshire 4 (6), Buckingham 2 (2), Chester 7 (5), Cornwall 6 (2), Cumberland 7 (1), Derby 2 (1), Devon 2 (3), Dorset *10 (7), Durham 4 (2), Essex 39 (31),* Gloucester 21 (23), Hereford 3 (0), Hertford 11 (4), Huntingdon 5 (0), Kent 33 (22), Lancaster 32 (24), Leicester 10 (4), Lincs, Holland 9 (0), Middlesex 18 (30), Norfolk 8 (4), Northampton 4 (4), *Northumberland 3 (0), Nottingham 11 (8), Somerset* 9 (6), Southampton 10 (4), Stafford 3 (1), Suffolk, East 3 (4), Surrey 14 (8), Sussex, East 4 (2), Sussex, West 2 (1), Warwick 16 (19), Wiltshire 8 (4), Yorks, East Riding 3 (2), Yorks, *North Riding 3 (3), Yorks, West Riding 48 (50),* Glamorgan 4 (7).

Following the precedent of 1947, the incidence of poliomyelitis should have fallen as autumn began. It has been suggested that the present rise has something to do with the unusual delay in the coming of weather: *has it perhaps been caused by the prol* of summer weather into October? This possibility no doubt be considered, with due regard to the plexities which arise when climatic changes have to analysed. Meanwhile we thought that prima-f evidence might be obtained by comparing the averages for hours of sunshine (in London) during summers of 1947 and 1949. The curves here r *do not, however, show any significant tendency* to those of poliomyelitis incidence.



In the U.S.A. (according to British United Press) Leonard Scheele, the surgeon-general, expects this to have the highest incidence on record, with a tota 40,000–45,000 *cases.*

Quarterly Statistics

THE JUNE QUARTER

The latest quarterly return [1] by the Registrar-Gene shows that in England and Wales the stillbirth-rate the June quarter, 1949, was the lowest for a June quar and equalled the lowest ever recorded for any quar

Births.—There were 4470 stillbirths registered the quarter, giving a rate of 22·7 per 1000 live and st births, *compared with 4746 and a rate of* 22·8 in t same period a year ago. The infant-mortality rate also the lowest recorded for any second quarter; dea of children under 1 year of age numbered 5691, repr *senting a rate of* 30 per 1000 related live births.

The number of live births registered was 192,1 giving a rate of 17·7 per 1000 total population, whi may be compared with 18·8, 21·9, and 19·1 in the seco *quarters of 1948, 1947, and 1946.* Of the births reg tered, 98,821 were males and 93,345 females—a proporti of 1059 males to every 1000 females. Illegitima births were 5·0% of the total, compared with 5 in the corresponding quarter of 1948.

Deaths.—119,984 deaths were registered during quarter, giving a rate of 11·1 per 1000 total populatio This compares with 110,257 deaths and a rate of 10 2 *the corresponding quarter of 1948.*

Natural Increase.—Births registered exceeded dea by 72,182, the corresponding natural increases for t second quarters of the years *1946, 1947, and* 1948 bei respectively 89,900, 117,181, and 93,336.

Survey of Sickness.—Out of 3541 men interviewed, 2 reported having had some illness or injury in February, there were 1775 consultations with doctors; out of women interviewed, 3379 reported having had some illn or injury in the same month, and there were 2413 consulta with doctors. Illness or injury of some kind during a mo *in the period January, February,* and March, was repor by 73·1% of all persons interviewed; the average incapac among all persons interviewed was 1·4 days per month. Amo housewives, 80·4% reported having had some illness or inj during a month, compared with the general level of 73·1

THE SEPTEMBER QUARTER

In the September quarter of this year the number *babies stillborn and the number dying* in the first y of life were the lowest for any quarter. In the follow table [2] the figures for this quarter are compared w *those for the same quarter in previous years.*

Third quarter, year	Live births		Stillbirths		Deaths		Deaths under 1	
	No.	Per 1000 total population	No.	Per 1000 live and still births	No.	Per 1000 total population	No.	Per 1000 related live births
1949	183,278	16·7	4104	21·9	101,207	9·2	4883	26
1948	191,858	17·5	4447	22·7	101,515	9·3	5514	28
1947	216,508	20·0	5073	22·9	97,099	8·9	7141	32
1946	213,051	19·8	5831	26·6	100,409	9·3	7100	33

PRIVATE PATIENTS AT HEALTH CENTRES

Mr. BEVAN moved an amendment to enable general actitioners to treat private patients in health centres. one time, he admitted, he had set his face against this posal because it was then uncertain what proportion the population would register with practitioners. w, however, the number of patients outside the scheme s so infinitesimal that no danger could arise to the ucture of the service. For this reason also, where health centre was available, the general practitioner ld not be expected to maintain a private surgery his private patients. Regulations to prevent possible crimination at the centre would be framed later. provision would be made that a doctor must have substantial number of patients in the public scheme ore he could avail himself of the private facilities the centre. The amendment was agreed to.

Mr. BEVAN moved a further amendment, which was o passed, to enable executive councils to make differial charges to general practitioners varying with the they made of the health centre for private patients. similar amendment to the Scottish Act was later ried.

Mr. BEVAN moved an amendment providing that Minister should indicate certificates that could be quired from medical practitioners. He said that some ne ago he and the Secretary of State for Scotland pointed a committee to weed out the number of tificates doctors were called on to provide. It was rly obvious that a little streamlining could be done. e committee had issued an interim report and the endment was designed to enable effect to be given to eir recommendations. The amendment was agreed to.

Mr. BEVAN moved a new clause providing that, except health centres, dentists should never be paid wholly mainly by fixed salary. He said that the purpose of e clause was to carry out in the case of dentists the me guarantees or undertakings that were advanced the case of general practitioners. The clause was ad a second time and added to the Bill.

Mr. JOHN WHEATLEY, the Lord Advocate, moved new clause to enable children in Scotland under the e of 16 to be treated as voluntary patients in mental spitals on the initiative of their parents or guardians. is had been the law in England since 1930 and it had rked well. The clause was read a second time and added the Bill.

THE DENTAL SERVICES

Mr. JOHN BAIRD moved a new clause prohibiting y dental practitioner, accepting patients under the ational Health Service, from taking remuneration m private patients. Two years ago he had fought for e liberty of the dental and medical professions to treat th public and private patients and he moved the new use with reluctance. But patients under the public rvice were suffering from the unethical practices of considerable number of dentists, and such rackets must stopped.

In the course of the lively discussion which followed, r. BEVAN declared that the dental profession had been ilty of worse conduct than any other profession in e National Health Service, but he was satisfied that ch misconduct was on the decrease. It was better, thought, to allow the disciplinary machinery established under the scheme to operate. He hoped that before ng good practice would drive out bad practice. The ause was by leave withdrawn.

TREATMENT FOR FOREIGNERS

Lieut.-Colonel WALTER ELLIOT moved a new clause roviding that foreigners who received medical attention nder the National Health Service while they were in his country should make some payment unless the ountry of their residence had made reciprocal arrangeents with this country. The Minister had said that e had made arrangements for immigration officers to urn back aliens coming to this country to secure benefits rom the health service, but that was asking these fficers to carry out a duty which they were not ompetent to perform.

Mr. BEVAN was amazed that it should be assumed o be wrong to treat a visitor to Britain. If we set an example there was every prospect that other nations would follow it. The health services of the whole world now were being stimulated by what was happening in Great Britain. But he agreed that if people came here from abroad to exploit the health service, that was quite a different matter. It was impracticable to impose on the Minister the duty of making regulations to recover from overseas visitors a charge for the use of the health service, and, moreover, if we passed such regulations we should turn our backs on centuries of British tradition. The new clause was by leave withdrawn.

ACCESS TO HOSPITAL BEDS

Colonel M. STODDART-SCOTT moved an amendment to enable a general practitioner or outside specialist to continue looking after a patient who had been admitted to a pay-bed in hospital. Practitioners were particularly anxious to treat their own maternity cases. Sir HENRY MORRIS-JONES said that Mr. Bevan had lately modified his views that there should be a strong line of demarcation between the general practitioner and the specialist, as shown by a recent Ministry circular urging hospitals to give more facilities to general practitioners. Mr. F. MESSER was sympathetic to the idea behind the amendment but could not support its present wording. He doubted if specialisation developed to its present extent was altogether good. No barrier should be placed in the way of improving the standard of the general practitioner. If that meant access to the hospital beds the opportunity should be given to the general practitioner, but in a different way from that proposed.

Mr. BEVAN agreed that there had been a tendency to dig too wide a gulf between the general practitioner and the specialist, but if that gulf was to be narrowed it must be done by agreement between the members of the profession rather than by legislation. What was really envisaged by the amendment was that a specialist not in the public service at all would be able to treat his private patient in a hospital. That was wholly wrong. It had been common ground that a specialist must have ready access to the hospital if he was to do his work properly. That was the reason for the argument against certain nursing-homes. If a specialist was not in the health service and not attached to a hospital, he would not be a person of permanent value in his calling and he ought not to have the facilities of the National Health Service. After further debate the amendment was negatived by 253 votes to 103.

GRADING OF SPECIALISTS

Sir HUGH LUCAS-TOOTH moved an amendment to give hospital specialists who were dissatisfied with any decision as to their grading the right to appeal first of all to a central professional committee and finally to the Minister. He did not say that the grading had been badly carried out, but a great many of those who had been graded felt that they had not been properly judged. The object of the amendment was to try to do away with that sense of injustice.

Mr. BEVAN said there was no academic qualification that corresponded in the medical profession to any hierarchical arrangement. And if according to the hierarchical conception the general practitioner was placed at the bottom, he did not agree with it. He insisted that the first-class general practitioner was the cream of his profession and we must not slip into the language of saying that any person was downgraded or upgraded in relation to whether he was further from or nearest to the status of a general practitioner. In so far as there were different scales of remuneration for people presumed to have different qualifications, the object had been to see that the salary alighted on the right person, so that when a general practitioner sent a patient to a specialist he was really sending his patient to a specialist and not to some person masquerading as a specialist. The task of classification was entrusted, on the advice of the medical profession, to a purely professional body. One of the defects of the amendment was that it suggested that after doctors had been classified by their fellows they should appeal to the Minister. Mr. Bevan added that, as they were classifying people on the grounds of their craftsmanship, particular, immediate, and precise knowledge was needed. Therefore it was a local committee

I wished—to spend my time even on writings for which there could never be a public. I have felt that to be no slight compensation. As you walk along Piccadilly, or up Bond Street, you will pass innumerable persons, most of them quite happy if the sun shines, who have written no successful books, nor ever thought of trying. Why then need I care if my books are none of them what people call successful: if in England I am known as a writer to the fewest?

Medicine and the Law

The Drugs in the Motor-car

A MEDICAL practitioner is required to keep dangerous drugs "in a locked receptacle which can be opened only by him or by some other person authorised." In Birmingham last January a medical practitioner drove to a cinema and left his car in a car-park close at hand, being careful to lock the car doors. Inside the vehicle was an unlocked leather case containing drugs to which the Dangerous Drugs Acts and Regulations applied. Coming out of the cinema at 9 P.M., he found that his car had been stolen. Three days later it was discovered at Walsall; its doors were open; the leather case containing the drugs was still on the back seat.

At the Birmingham police-court he was fined £5 for having failed to keep the drugs in a locked receptacle. The stipendiary magistrate declined to accept the argument that a locked motor-car is a locked receptacle. This decision has now been confirmed by the High Court, to which the doctor had appealed. The Lord Chief Justice[1] conceded that a motor-car might perhaps be described as a receptacle for luggage, but the regulation must be construed in a way which would effect the obvious purpose of the legislature.

By this time the appellant is probably wondering what is the judicial conception of luggage; a suit-case, it seems, is luggage if it contains a tooth-brush and a pair of pyjamas, but not if it contains drugs. "Receptacle," according to the *Oxford English Dictionary*, is "that which receives and holds a thing: something into which another thing may be put: a containing vessel, place or space: a repository." The attention of the court must have been drawn to the dictionary definitions, but the judges prefer a narrower interpretation in their zeal to give effect to what Parliament obviously intended.

One seems to remember that judges ordinarily decline to study the pages of *Hansard* or to speculate on what our legislators must have meant; judicial minds usually confine themselves to what Parliament said, rather than what Parliament intended. All that Parliament said in the Act of 1920 was that the Home Secretary might make regulations about the manufacture, sale, and possession of dangerous drugs. If legislators had been asked their intention at the time, the answer would probably have been that the drugs must be kept safely under lock and key, out of the reach of children or of any casual person who might be tempted to poison either himself or other people. Did any M.P. consider in 1920 whether a locked case in an unlocked car is safer than an unlocked case in a locked car? The "locked receptacle," of course, is not the language of Parliament but the language of the Home Office regulations; the regulations are just as much the law of the land as is a statute, provided that they do not exceed the powers granted by the parent Act; if the doctor's appeal had succeeded, another amending regulation could promptly have prescribed that, for the purposes of the custody of dangerous drugs, the word "receptacle" shall not include a motor-car.

What then must the practitioner do, since the authorities which enforce the law seem powerless to prevent his car from being stolen? Perhaps he can fit a lock to some pigeon-hole in the front of his car, so as to equip himself with an itinerant poison-cupboard. Many doctors, it must be confessed, carry on their persons a small hypodermic case containing enough tablets of alkaloids to kill a dozen people. Often enough their services are needed in an emergency—for instance, to administer morphine to someone pinned beneath an overturned omnibus. Coat pockets cannot be locked receptacles. There are, however, some saving words the Dangerous Drugs Regulations—words introduced our researches have not misled us) in an amen a year ago. To the general insistence upon a locked receptacle for drugs "in the actual custody" of authorised persons there is a sensible exception which covers occasions "when the necessities of the practice of profession, functions or employment require." Does not professional practice require that the practitioner shall hold himself reasonably ready and equipped to give relief to possible patients in any emergency? Or will the public be satisfied, when the services of a doctor are called for in some accident, with the answer "I am sorry, I am not carrying my locked receptacle"?

Parliament

National Health Service (Amendment) Bill

IN the House of Commons on Oct. 19, this Bill as amended in Standing Committee was considered on recommittal. Mr. ANEURIN BEVAN accepted a new clause, moved by Mr. H. Linstead, which introduced a system of interauthority accounting for the ambulance services.

HOW MUCH SHALL THE PRIVATE PATIENT PAY?

Mr. A. J. P. HOWARD moved an amendment to the schedule providing that private patients instead of being required to pay the whole cost of hospital treatment should be allowed to pay only a proportion of that cost. Mr. BEVAN held that the amendment if accepted might give rise to resentment on the part of those who objected to benefits being given to different classes of patients in the public hospitals. There must to some extent be a hang-over from the past, and time would be needed to eliminate certain habits of mind. But he believed that the tendencies were all in a healthy direction and that before many years had passed there would be no sense of discrimination or unfairness in the hospital administration. If the private patients were charged twice, after all that was their fault. Having made a contribution through the taxes to the National Health Service they elected to go outside that service. Furthermore the proposal in the amendment would add to the cost of the service.

Mr. J. A. SPARKS pointed out that some patients elected to be treated privately because they could get into hospital much more quickly that way. Mr. BEVAN replied that he would be unhappy to learn that anybody had been able to pay his way into a hospital ahead of another patient who could not afford to do the same. Even so this was no argument for the amendment. It merely meant that we must provide additional hospital accommodation.

Mr. LINSTEAD declared that one of the principles of the service was free choice of doctor. In the general-practitioner service that principle operated fully. But the only way to get the specialist of one's choice was to become a private patient. Again there were something like 500 hospital management committees in the country and probably 1500 or 2000 hospitals with private beds. There were something like 1500 possible variations in the weekly charge according to the upkeep costs of each institution. Could not the Minister at least fix a standard charge?

Mr. BEVAN interposed that at least 40% of the pay-beds were occupied by free patients, which was a tribute to the way in which the administration was carrying out the terms of the Act.

The amendment was negatived by 256 votes to 139.

In England Now

Running Commentary by Peripatetic Correspondents

WITH me the pursuit of civic virtue is a positive ssion. I'm funny that way. There's hardly an action perform without asking myself. "Does this help or nder the Country in her present plight. or is it. from e standpoint of civic morality. strictly neutral?" u would expect—if you were sufficiently interested—at I might wear a careworn expression, and you would right. The trouble with us would-be-goods is that we n't get enough guidance from the Government. They l us to work harder and not to ask for more pay. ey ration us. They compel us to pay taxes. But ey don't tell us how to behave in a whole lot of other ys. During the war. the good life was so much easier live. By the eating of a surfeit of potatoes. for example. e acquired a degree of spiritual merit which more an offset the concomitant physical discomfort. But wadays one cannot be sure how much, if any. one ght to consume of things unrationed. Ought we. eally, to give up smoking or (assuming we can afford smoke) ought we to smoke more or less American or npire or homegrown tobacco? Ought we to save all e money we can (if we can) and invest it in Government curities? Ought we to spend all we can on enterinment, or nothing at all? Should the good citizen) go dry. (*b*) drink foreign or Empire wines. or (*c*) stick to er or spirits? Or doesn't it matter a tinker's cuss? es, I was afraid that might be the answer.

* * *

I have always wanted to bring up my children scien- fically: so I went to Roffey Park last weekend for the urse inspired by the Institute for the Scientific Treat- ent of Delinquency. My impressions are confused. I n relieved that I have no twins. because it seems impor- nt that they must be placed alternately in the stern the pram to avoid subsequent retaliation on Society. wanted to ask if the "Get forrard you scum" so often n the lips of the Pirate Chief is really a projection of his wn resentment over relegation to the bows of his pram. ut the analysts might have taken it seriously. How ght they seem to be when Dr. Glover is expounding. ut how worrying it all is to a parent!

It was not really like that. The atmosphere of the eekend was essentially practical. Begun by Mr. Claud lullins it could hardly fail to be. In reporting on a elinquent the essential thing, apparently. is to know ne Bench you are advising. Most magistrates are com- letely ignorant of psychiatric terms and are irritated y them. We were also warned that we must never hallenge "punishment": at the most we should restrict urselves to doubting its use as a deterrent in the parti- ular case. Magistrates are also irritated by the word opinion" because it has a specialised. more precise eaning to a lawyer. Several speakers felt that psychi- try was being brought into disrepute by overoptimism, n inevitable result of propaganda on its behalf. It was uggested tentatively more than once that Mr. Mullins imself is too sanguine in his faith in psychiatry. He is ot altogether to blame for this—as one speaker put it, We have sold the magistrates a line and they have alled our bluff." Dr. Alan Maberly underlined this when e advised us to "err on the side of modesty, caution, nd pessimism" in our reports. He also made the mportant point that although we may not be able to cure he patient. psychiatrically speaking. we may be able to hange his delinquent symptoms into less antisocial ones. Miss Cicely Craven dealt with the functions of the juvenile courts and their disadvantages. and described the changed circumstances under the Criminal Justice Act.

A holiday from delinquency took place on Saturday evening when we saw Roffey Park's own propaganda film. Dr. Ling, the centre's director. converted what seemed an oddly hostile audience into an enthusiastic one. His claim that Roffey follows the Greek idea of beauty and peace as good medicine is certainly reflected in the surroundings. The jangled nerves of any industrial worker should be rehabilitated (please note. Mr. Ed., that it is not Roffey Park *Reablement* Centre yet) among those beautiful trees. The centre itself is a converted country house of great charm. Our own quarters were also delightful and I can thoroughly recommend Dr. Ling's offer of them to any appropriate organisation wishing to use them for a weekend course. The food was good, too. I noticed that the programme printed the lectures in small letters and DINNER, COFFEE, and so on in block capitals. The right attitude to food. I feel. Yes. the Greeks would be pleased with Roffey Park. but only the Spartans would like the bath water. It was unfortunate that the rain which pelted on us all the weekend should have flooded the boilers.

A discussion one evening split us into three groups: the mental hospital group under the cunning leadership of Dr. MacKeith appropriated the fire (and Mr. Mullins). It was noticeable how we all seemed to have the same problems. During the small, spontaneous discussions which cropped up during the weekend your reporter found that whenever he detected the glint of battle in somebody's eye, and he crept up with pencil poised over notebook to record an anti-delinquent pearl. the conversation seemed to be about grading.

Altogether a very pleasant weekend.

* * *

After five years in the Navy and four years' whole-time in dermatology I have ventured into rural general practice. On departing from my teaching hospital my wise colleagues raised their hands in horror: "What will you do about midder?" they asked. The answer is that in my two months of practice I have done no midwifery; the district midwives have done it for me. On the other hand. I've seen a lot of skins—a fifth of my patients. I would say.

My very first visit was to a case of vulval herpes which I sent to hospital as such. because it was secondarily infected. The houseman receiving it said on the phone that it must be gonorrhœa, but he had not seen the other three cases of herpes I had seen that morning. A girl with urticaria pigmentosa had baffled her neighbours. but she was delighted when I wrote the name on a piece of paper for her and showed her the picture in *Sutton*. Impetigo abounds. as does animal ringworm. I have learnt that pig fleas may so bite a child as to give it a generalised papular eruption as widespread as measles. A cowman produced an infected hand and asked whether it was cowpox: we read *Sutton* together before we could answer that one. I have of course been too clever. I told the local barber that his child's rash was bed-bug bites. He went straight from my surgery to the rival firm where he got the answer he wanted—"blood out of order." and a bottle of pink medicine. Doubtless the bed-bugs will like the medicine. while the barber's customers will be told how ignorant is the new doctor.

I now have a question to ask my gynæcological friends when they venture into practice: "What will you do about skins?"

* * *

Anæsthetists are such observant people. My friend discovered that tickling the sole of his anæsthetised patient's foot produced a response. in the shape of foot-wiggling, a few seconds before the patient really woke up and began to vomit. Immediately recognising the importance of this fact. he constructed an ingenious apparatus which, he believes. will make all other anæsthetic apparatus obsolete. This is an automatic tickler which gently caresses the sole of the foot with a feather at regular intervals. The minutest wiggle of a toe immediately operates a gadget which injects another dollop of thiopentone into the drip. The patient then sinks back to the depths of anæsthesia and everybody is happy. Anæsthetists will be freed from the present annoying interruptions from patient or surgeon which make it impossible for them to give their full attention to reading the newspaper.

* * *

The distressing gastronomic experiences of your Peripatetic in Sweden were surpassed by those of a colleague who returned from a visit to Central Europe suffering. he said. from Acute Wiener Schnitzophrenia.

* * *

I have a patient who keeps swallowing nails. Is he a nailphile?

that did the classification. Further, the review was being done for the first time in the history of medicine and they were denied precedent. As the first review was bound to be empirical they had decided that a further review—not an appeal—should take place. A person could if he wished have his case referred to a committee of two people outside his region.

Dr. H. B. **Morgan** had always been in favour of some recognised scheme by which specialists and the different grades in the profession can be recognised. But while he had considerable sympathy with the amendment he did not agree with the whole of it. He asked the Minister to look at this problem with a view to meeting this great difficulty in the profession; to see whether some body, professional or mixed, could be brought into being to clean up the profession in a way pleasing to those most competent within it.

Lieut.-Colonel **Elliot** emphasised that a sense of grievance did exist. Many people felt a grave sense of uneasiness and dissatisfaction because of an anonymous decision. He thought that to set up some body, not the local body, would be an advantage, so that people would not be appealing to the same committee again even with two added members.

The amendment was negatived by 241 votes to 97. The report stage was ended and the Bill was read the third time and passed.

The Nursing Profession

On Oct. 21 the Nurses Bill [1] was read a second time. The Nurses (Scotland) Bill had been read a second time the previous day. Both measures were introduced in the House of Lords.

QUESTION TIME

Sickness and Disablement Statistics

Mr. **Rhys Davies** asked the Minister of National Insurance if he was aware that under the approved-society system societies arranged statistical data showing periodically the incidence of sickness and disablement among their membership, separating males and females for the purpose; and if he would give similar details showing any disparity between the statistics under the old and the new system.—Mr. **James Griffiths** replied: Arrangements have been made to collect and publish periodically comprehensive statistics of sickness experience under the National Insurance Acts. But comparison with the figures obtained under the old system will not be possible as detailed statistics were only available in respect of a few approved societies.

Sickness-benefit Claims

Sir **Waldron Smithers** asked the Minister what steps were being taken to supervise sickness claims and to prevent abuse of the provisions of the insurance and health services.—Mr. **Griffiths** replied: The steps taken to supervise sickness-benefit claims under the National Insurance Act are broadly the same as those followed by the approved societies under the old National Health Insurance scheme—namely, careful scrutiny of claims, sick visiting in selected cases, and the use of the regional medical service of the health departments to obtain second medical opinions in cases of doubt.

Doctors' Remuneration

Sir **Ernest Graham-Little** asked the Minister of Health under what sanctions executive councils were subjecting medical practitioners in the National Health Service to a heavy tax upon their payments from the service if they refused to undertake a large panel.—Mr. **Bevan** replied: The regulations governing the remuneration of general practitioners provide for the adjustment of remuneration in the case of a practitioner who is exempted from the liability of having persons assigned to him and is relieved of obligations for emergency night calls in respect of persons not on his list. There is nothing to stop a practitioner limiting his list without applying for these exemptions.

Beds in Children's Hospitals

Sir Ernest **Graham-Little** asked the Minister how many children's hospitals had been closed, or the number of beds in children's hospitals diminished since the National Health Service came into operation; and what was the present number of children's beds in special hospitals and in general hospitals respectively.—Mr. **Bevan** replied: No children's hospital has been closed since the coming into operation of the National Health Service, although two are no longer used exclusively for children. The total number of children's beds available has increased by 1278. The number of children's beds available in general hospitals is now 16,449 and in special hospitals, 23,302.

School Dental Service

Sir **John Mellor** asked the Minister of Education whether he had considered the resolution, unanimously adopted by the representative board of the British Dental Association, criticising his department for failure to provide a facilities for treatment of oral sepsis among school-c and what improvements he was making in con —Mr. **George Tomlinson** replied: The school dental service has been affected by difficulties over the salaries of dentists employed by local authorities. Negotiations are proceeding with a view to the formation of a Dental Whitley Council and the Minister of Health and I are hopeful that agreement will soon be reached on its formation. Once this is done I hope that, with the prospect in view of a salaries settlement, the school dental service will be restored to its former efficiency.

Slot-machine Sales of Contraceptives

Replying to questions by Sir **Henry Morris-Jones** and others on the danger to public health likely to result from the sale of contraceptives from automatic slot-machines, Mr. **Chuter Ede**, Home Secretary, stated: I have come to the conclusion that the social mischiefs involved are so serious as to require immediate action. I have accordingly given instructions for a model by-law to be drafted prohibiting the sale of contraceptives by means of automatic machines. This model by-law will be circulated to all county and borough councils for their consideration, and, if adopted, will be subject to confirmation by me.

Spectacles

Replying to questions, Mr. **Bevan** said that there were still delays in supplying spectacles of anything up to six months or so, but by no means all cases took as long as that, and better supplies were improving the position steadily. The number of spectacles ordered in the two years ended Sept. 1, 1948, and 1949, were respectively 4·5 million and 9·9 million.

Food-poisoning

In answer to a question Mr. **Bevan** stated that the number of outbreaks of food-poisoning reported from 1935 to 1938 were respectively 137, 82, 94, and 156; and from 1945 to 1948, 422, 598, 765, and 964.

Help of Protection Societies

Sir **Ernest Graham-Little** asked the Minister why he had refused the assistance of the Medical Defence Union to doctors who were accused before the medical services committee of professional negligence; and whether he would withdraw this prohibition.—Mr. **Bevan** replied: The regulations permit a party to an investigation by any service committee of an executive council to be assisted in the presentation of his case by some other person, provided that no person shall be entitled, in the capacity of counsel, solicitor, or other paid advocate, to conduct the case for any party by addressing the committee or examining witnesses. I see no reason to alter these arrangements.

Care of Young Cripples

Mr. **Walter Fletcher** asked the Minister of Health what local authorities had made provision for the housing and care of young crippled persons who had completed their schooling at Shaftesbury or similar homes.—Mr. **Bevan** replied: Residential accommodation for persons in need of care and attention not otherwise available to them is provided under the National Assistance Act by local authorities in homes managed by themselves or by voluntary organisations. I am not aware that any local authority has established a home for cripples. My advisory council is considering what guidance might be given to local authorities on the welfare of handicapped persons generally. Meanwhile my regional welfare officers will give what help they can in individual cases.

---

[1] See *Lancet*, 1949, i, 842, 938.

d conjugates, and the quantity required to be hydro- ed for the maintenance of health and normal blood-formation is probably less than 1 mg. daily. Moreover, normal individual is capable of obtaining this quan- y of free folic acid from the small amounts of folic-acid jugates in the food despite the fact that natural ds are often rich sources of conjugase inhibitors. If atient with pernicious anæmia were able to obtain r 2 mg. of free folic acid daily from his food he would develop a megaloblastic anæmia, for it has been wn that the oral administration of folic acid in these all quantities will transform the megaloblastic bone- rrow back to the normoblastic state. Since there is satisfactory evidence to suggest that addisonian nicious anæmia is a direct dietary deficiency disease, follows that a megaloblastic anæmia develops in this dition *because the patient cannot procure, from* the tural foods which he eats in normal quantities, the all amount of folic acid required for the maintenance normal blood-formation. It would appear to be a sonable assumption that this failure to procure free ic acid from natural foods must be closely linked with production and absorption of vitamin B_{12}, which in m is directly related to the secretion of Castle's rinsic factor by the stomach. The mechanism by ich vitamin B_{12} enables the normal individual to tain or utilise free folic acid is unknown. Whether is effect is produced by a mechanism working in parallel es or in series is also unknown. Without further owledge all that can be suggested at the present time that vitamin B_{12} may act by facilitating the release of lic acid from the conjugates present in natural foods, alternatively, it may promote their absorption and ilisation in some manner as yet not determined.

In considering the pathogenesis of the megaloblastic æmias it is essential to remember that in certain cases sociated particularly with malabsorption, malnutrition, id pregnancy, and occasionally in cases for which no tisfactory explanation is available, the response to the renteral injection of potent liver extracts may be poor absent. This finding has been confirmed during the ist year by distinguished hæmatologists in America ho have recorded megaloblastic anæmias refractory to ie parenteral injection of vitamin B_{12}. In a paper on le megalocytic anæmias published in THE LANCET 949, i, 295) Dr. Wilkinson insinuates that the refrac- riness to liver extracts reported in recent British ublications by experienced hæmatologists can be largely xplained by a failure of the authors to take the ele- entary precaution of using potent liver preparations. his insinuation is quite unwarranted. Moreover, he rther confuses the problem of refractoriness to liver xtracts by stating that he has never seen uncomplicated ases of addisonian pernicious anæmia refractory to otent liver extracts, thus suggesting that the case- eports describing refractory megaloblastic anæmias elong to the category of addisonian pernicious anæmia. o such suggestion has ever been made by myself or ny of my co-workers in this field. In fact, a failure to espond to adequate doses of potent liver extracts or B_{12} ould be considered by myself as the best possible proof hat the patient was not suffering from addisonian ernicious anæmia, since the primary fault in this con- ition is a deficiency of vitamin B_{12} and this would be utomatically corrected by parenteral replacement herapy. On the other hand, in cases of megaloblastic næmia refractory to potent liver extracts or vitamin B_{12} t is reasonable to assume that the fault does not lie in deficiency of vitamin B_{12}—otherwise it would be orrected by the administration of this factor—but is elated to a defective intake of the conjugates of folic cid in natural foods or to a failure in their absorption r utilisation for reasons not understood. On this basis t is possible to explain why all cases of addisonian pernicious anæmia respond to vitamin B_{12} while other patients with a megaloblastic bone-marrow, identical in appearance with that found in addisonian pernicious anæmia, can be partially or completely refractory to this vitamin. In my experience and in the experience of many leading American hæmatologists whom I recently consulted, every case of megaloblastic anæmia will respond to free folic acid, although in some cases continued maintenance treatment may not sustain a normal blood-level. This is what I would expect if the assumption is correct that the ultimate factor in the maintenance of normoblastic blood-formation is free folic acid. I have only been able to find in the literature records of some 3 or 4 cases in which it was claimed that a failure in response to free folic acid occurred and was then followed by a response to liver extracts. This is an extremely *small number of reported failures when one* considers the thousands of cases which must have been treated with folic acid. Moreover, the case-reports were not all sufficiently documented to permit an accurate assessment of the data given.

Much more work will have to be undertaken before the vexed problem of the interrelationship of folic acid and vitamin B_{12} is solved, but with the present knowledge available it is my belief that both folic acid and vitamin B_{12} are required for the prevention of megaloblastic blood-formation. Finally, I submit that a careful scrutiny of the data presented by Drs. Wilkinson and Israëls in your issue of Oct. 15 does not warrant their deduction that patients with addisonian pernicious anæmia have a normal capacity to release free folic acid from its conjugated forms, or that folic acid or its conjugates play no major part in the ætiology of the human pernicious-anæmia syndrome.

STANLEY DAVIDSON.

VACCINATION UNDER THE N.H.S. ACT

SIR,—In his letter of Oct. 22 Dr. Killick Millard takes me to task for "begging the question" of infant vaccination in the concluding paragraph of my article in the October number of the *Monthly Bulletin of the Ministry of Health and Public Health Laboratory Service.* Dr. Millard's dislike of infant vaccination is well known. Unfortunately the evidence on which his views are based, and also those of many who disagree with him, is frequently distorted by less critical persons who seek to discredit not only infant vaccination but all vaccination against smallpox, and incidentally immunisation against diphtheria as well. This accounts I think for a certain reticence, which might appear at first sight to be "question-begging," in the references to this subject in official and other publications.

In my article I did not attempt to discuss the pros and cons of infant vaccination and certainly did not intend to minimise its difficulties and dangers, of which I am well aware, as may be seen from an article on *postvaccinal encephalomyelitis in the April, 1948,* number of the same *Bulletin.* During the past eighteen months I have met doctors concerned with the control of smallpox in Holland, France, and other European countries as well as in the United States and Canada. All of them I found were aiming, though with varying success, at a well-vaccinated child population as an important part of their own national defence against smallpox. I was therefore concerned in my recent article to set out in some detail the current position of infant vaccination in this country and to point out that by our apparent neglect of this procedure we are giving the impression abroad that we do not regard protection against smallpox as a serious matter at the present time. I submit that the paragraph quoted from my article can and should be read in this sense.

Letters to the Editor

ROYAL MEDICAL BENEVOLENT FUND

SIR,—Extra comforts at Christmas time are a great help in time of need—the little extra coal, the urgently needed warm clothing, the wherewithal to provide a real Christmas dinner. I appeal to members of the medical profession to bring these comforts to their less fortunate professional brethren, or to their widows and children who are beneficiaries of the Royal Medical Benevolent Fund. Not only will gifts bring them comfort and cheer, but their hearts will be warmed by the kind thought for them.

I hope that all, whether subscribers to the Fund or not, will send donations to provide this little extra cheer, and that those who are not subscribers will become regular supporters of the medical profession's own benevolent fund.

Donations and subscriptions, marked "Christmas Gifts," should be sent to the Secretary of the Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, Putney, London, S.W.15, and will be gratefully acknowledged.

WEBB-JOHNSON
President.

ACUTE MASTITIS

SIR,—We read with interest and appreciation Mr. Walsh's article in your issue of Oct. 8, but note that he regards treatment by aspiration, after a trial with 5 cases, as inefficient.

During the past twelve years or so some 300–400 cases of breast abscess have been treated by aspiration at this hospital. First, before penicillin was available, aspiration was performed often 2–3 times a day; then penicillin came in and was used to fill the cavity; and finally systemic treatment came with the purer forms of penicillin (as well as the local treatment), 300,000 units of procaine penicillin being injected twice daily.

During this period only one or two cases have had incision before aspiration had been tried. The advantage of aspiration is that the patient need not be admitted to hospital unless her temperature be high. Except for a few cases where the organism was other than *Staphylococcus aureus* (there were 2 cases of proteus infection) the condition has usually been cured in 7–14 days; and the cosmetic results are almost perfect, the breast returning to normal.

Breast-feeding was not stopped unless pain was excessive, or the abscess was too near the nipple and unpleasant for mother and baby. In the vast majority of cases no pain or discomfort is felt with aspiration under local anæsthesia.

Lewisham Hospital,
London, S.E.13.

LIMITATIONS ON PRESCRIBING?

SIR,

"Aristotle thought that if the individual was not allowed to choose his physician but must go to the one assigned to him by the magistrate under a law, it would be necessary for the law to fix the definitely prescribed prescription for every ill."

"A committee, headed by Sir Henry Cohen, was drawing up a list of drugs that could be provided by general practitioners."

The first statement was made by Dean Pound in an address given before the Massachusetts Medical Society; the second is attributed to Mr. Bevan.

It has long been felt that the increasing cost of the medical service would impose upon the authorities the need to find ways and means of reducing the financial burden to the State. Are we to infer from the Minister's statement that he is going to impose upon general practitioners a formulary which it is compulsory for them use? Or is it that the formulary will bear a reference: "Herpes—turn to page 5—only the following drugs may be used." ?

I deny any suggestion that Sir Henry Cohen or his colleagues have the intention of imposing upon doctors any such patronising tutelage. Nevertheless I have a disturbed feeling that the statement, "that could provided by medical practitioners," might be altered by regulation to "that must be provided. . . ." If this intention is absent, then I doubt the wisdom of assessing the value and the specificity of the multitude of drugs, both proprietary and otherwise, which are in common use. Perhaps it would be helpful if more reasons could be stated for setting up the committee, and if its could be defined.

Hove.

STANLEY KAYE.

*** The facts for which our correspondent asks will be found on p. 805.—ED. L

FOLIC ACID AND ITS CONJUGATES IN THE PATHOGENESIS OF MEGALOBLASTIC ANÆMIA

SIR,—In your issue of Oct. 15, Dr. Wilkinson and Dr. Israëls report hæmatological responses which occurred in patients with addisonian anæmia who were given a synthetic preparation of a naturally occurring pteroylglutamic-acid conjugate (teropterin). From the data obtained from this investigation they claim to have shown that "there is thus no reason for supposing that in pernicious anæmia there is a failure to release free folic acid from its conjugated forms." In addition they state that ". . . the newer evidence . . . seems to suggest that with present knowledge neither folic acid nor its conjugates play any major part in the ætiology of the human pernicious-anæmia syndrome." In view of the importance of these sweeping statements, if proved to be correct, it seems advisable to scrutinise closely the data on which they are based.

Treatment of 8 patients with addisonian pernicious anæmia with large doses of teropterin produced a satisfactory hæmopoietic response in each instance; 7 out of the 8 cases received this synthetic folic-acid conjugate in initial amounts of 80–140 mg. daily. The only conclusion which I submit can be drawn from this finding is that under the conditions of the experiment patients with pernicious anæmia can liberate sufficient free folic acid to produce a hæmopoietic response. The amount of free folic acid released is however not known, but it might be as small as 1 mg. per day, since I have shown that this amount can produce a hæmopoietic response comparable to those obtained by Wilkinson and Israëls with the large quantities of teropterin administered. Since no attempt was made by the authors to compare the ability of patients with pernicious anæmia and normal individuals to release folic acid from teropterin in the large quantities given (as could be done by assaying the excretion of folic acid in the urine in both groups), there is no justification for the deduction that the capacity of a patient with pernicious anæmia to utilise folic-acid conjugates is not impaired. There is in fact evidence that the reverse may well be the case. Thus the reports of Bethell, Swendseid, and others mentioned in Wilkinson and Israëls's paper clearly show that when concentrations of folic-acid conjugates prepared from natural sources are given to patients with pernicious anæmia in quantities more nearly approaching those present in the natural diet, and containing traces of natural conjugase inhibitors which prevent the cleavage of folic-acid conjugates, the hæmopoietic response may be absent or weak and inconstant. Such experiments much more nearly reflect the nutritional problem as it occurs under normal conditions in man. It is generally agreed that natural foods contain very small quantities of folic-

REGIONAL CONSULTANT.

THE DISTINCTION AWARDS

—I have studied your leading article last week
interest and with the hope—soon killed—that I
find therein, what I have not been vouchsafed
y evasive critics, a reasoned answer to the objections
e voiced in another place. As I read it, you have
y provided further indications of the fallacy of this
ely grading affair. "There are bound to be
kes"; "the merit of doctors, like the merit of
and artists, is not always quite apparent"; and
, le mot juste, "rank is but the guinea stamp."
is precisely what a Government distinction issue
be, and no more.

vertheless your article in sweetly reasonable fashion
eds to the cliché that the "only convincing test is
ience." "Experience" is an impressive word.
he skilled experimenter knows what is and what is
ikely to be a good experiment. for he has thought
is problem beforehand and has so devised his experi-
that it shall yield him the most unequivocal answer
ble. What is to be said of this grading "experi-
"? The experimenters are an ad-hoc committee
n by that austere experimental genius the Minister
ealth, and not by any representative medical body
d in the field of inquiry. The procedure the com-
e have adopted gives no clue that they have sought
fine the quality that they are asked to grade, or
asked themselves if it be definable. The burden
ding in its vital preliminary stage has been passed
vast number of overlapping bodies, of diverse
ers and infinite variety, which are now proceeding
eir unwelcome task by whatever makeshift device
can think of. The only common item in method
to be a profound secrecy. Ballots and lists are
compiled and passed on with every juvenile device
stery to accountants and the like to boil down into
sort of coherence and then to pass on—still secretly
the Awards Committee. The potential gradee is
elf given an opportunity of dilating upon his merits
printed form, and without being a cynic one may
assume that he is as anxious not to let his colleagues
is homework, as they, when they compile their
reports, are to keep the results of their academic
rches from him.

e whole process is as chaotic as it is undignified.
everyone who participates in it is distressed at the
he has to play, and resents the circumstances which
placed him where he is in the matter. To call
n experiment is a travesty of words. and to expect
quitable or rational result is to be irresponsible.
hat can the general practitioner, in whose merits
ew masters are not interested, think when he sees
consultant thus tempted and thus responding to
ure of the pay warrant ?

nally, to turn to the undergraduate wisecrack with
h your article so fitly ends, I ask, who within the
ssion has ever judged the consultant by his
rial splendour or his chromium-plated chariot ? At most these exquisites, who loom so large in the minds of those who do not practise medicine, have never been more than a minute fraction of the consultant body, and if this "experiment" in grading can have nothing better to be said for it than that it will do away with standards which have never been taken seriously by us. then it stands already condemned, for it is as unnecessary as it is futile and unworthy of a learned profession.

London. W. 1. F. M. R. WALSHE.

** Our suggestion was that the Spens Committee's proposed system of paying specialists—by salary and distinction awards—should be tried for five years, "after which consultants as a body could themselves decide whether it be discontinued or altered." This can. we think, be fairly described as an experiment, in the *O.E.D.* sense of "a procedure adopted in uncertainty whether it will answer the purpose."—ED. L.

SIR,—Lord Melbourne remarked pleasantly that a singular distinction of the Order of the Garter was that there was no damned nonsense about merit in its award. Unhappily Lord Moran's committee can claim no immunity from the vulgar task of assessing the relative worth of candidates for distinction, and I am therefore encouraged to suggest to them a plan which may alleviate their embarrassment in becoming at once a fount of honour and distributors of pecuniary incentive.

The principal danger that besets them is that their attempt to assess consultants in order of merit may not merely entail injustice to individuals but lead to ill-feeling between them and stimulate log-rolling and self-advertisement among the less scrupulous. That. you will readily agree, would be disastrous.

As I see the position, the committee. when it comes to grips with the problem, will find that for the highest grade of award there will be a small number of candidates who deserve it beyond question by any sensible person. With them there is no difficulty. They should have it. But for the remainder of the awards in this group there will be numerous men whose distinction it is quite impossible to assess in any equitable order of merit for the reasons that Walshe has already published. that you. in your leading article, find so convincing, and that I, therefore. need not recapitulate.

My suggestion is that these awards should be determined by lot. Those whom fortune favoured would have the highest award and the remainder would automatically receive the award of the next grade. This process should be repeated for each of the groups. An Englishman will accept misfortune in a lottery with good grace and good humour, but he will resent deliberate classification in a grade inferior to that of a colleague as an injustice.

Do not regard this suggestion as frivolous. I believe that a ballot in the conditions I have outlined would reach as fair a result as the committee's longest and most earnest deliberations (for Walshe is right. I hold. except in respect of the few whose work is of unquestionable distinction). You will notice. of course, that the plan does not wholly surrender the distinction awards to blind chance : the judgment of the committee operates in the selection of the names to go into the hat and in the choice of those who are so outstanding that they are removed from the ballot.

The confusion and suspicion that already exist are evidence enough that the plan for a Central Awards Committee is unsatisfactory, and my suggestion is merely a temporary expedient to deal with an immediate and pressing difficulty. The Spens Committee presumably acted in the belief that a consultant at Much-Binding-in-the-Marsh might be the equal of a consultant at Guy's : in ninety-nine cases out of a hundred that has been false in the past and will remain so in future, but it must be admitted that men of promise have occasionally been excluded from competition for posts of distinction

NIPPLE-SHIELDS

SIR,—If one rubs a finger on a lead nipple-shield the skin is blackened; the removal of the black lead-stain with soap and water necessitates vigorous washing. Moreover milk which has been in contact with lead has been shown to contain lead. Hence wiping the nipples with a damp cloth before feeds certainly cannot be assumed to eliminate the danger of lead poisoning for a baby whose mother uses these shields; and vigorous scrubbing with soap and water five times a day would scarcely seem good treatment for a cracked nipple. Printed instructions that the shields should only be used, say, for a week might of course be issued; but who knows better than a doctor that instructions are not always read and that advice is not always followed? We have plenty of evidence that mothers find lead nipple-shields comfortable, which only increases the danger of their prolonged use. Surely the Ministry of Health is to be congratulated on taking steps to prevent the tragedy of a mother in this way unwittingly poisoning her infant with lead, and so, perhaps, causing death or mental defect. After all, there are other ways of treating cracked nipples.

Mr. Whitehead and I have read with much interest Dr. Kenwin Harris's letter last week on the dangers of some plastic materials. Is it not a fact that small articles, such as nipple-shields, can be manufactured from plastics containing no plasticiser nor any other toxic material? Can Dr. Harris—or the manufacturers—tell us whether the plastic shields now on the market are known to be non-toxic?

Queen Elizabeth Hospital for Children,
London, E.2.
I. GORDON.

SIR,—Dr. Kenwin Harris rightly warns in his letter last week that not all plastic materials could be considered suitable for nipple-shields. We wish to assure prescribers that the plastic material used in the manufacture of the 'Woolwich' breast-shield is 'Polystyrene' and is free from lead or other toxic substance.

Allen & Hanburys Ltd.,
London, E.2.
B. E. KENT
Public Relations Officer.

CONTROL OF TUBERCULOSIS

SIR,—Dr. Temple Clive writes, in his letter last week, as a sanatorium physician. Patients do not come under his care for treatment until perhaps one year after the diagnosis of tuberculosis; and his outlook must therefore be very different from that of the chest physician, who has to look after the patient at home during a wait of so many months.

It is right to "precondition" a patient by bed rest for 3–6 months, but not for one year. Collapse therapy at home makes the patient feel that something is being done and that he is not just being left to deteriorate. This has considerable effect on morale. Pneumoperitoneum, with or without phrenic crush, can produce excellent results at home, and has practically no complications. I would fully agree with Dr. Temple Clive that the "crash" pneumothorax without adequate bed rest beforehand is to be avoided. There comes a time, however, when a patient has been in bed for 3–4 months and has reached the right condition for the induction of a pneumothorax. To delay this for six months until the patient can be admitted to sanatorium may in a great many cases make a pneumothorax impossible, and the patient then has to have major surgical treatment. There will be failures and complications arising from the home-induced pneumothoraces, but such things are not unknown even in a sanatorium; at least, by attempting a pneumothorax on the right type of lesion at the right time, the chest physician may give the patient a chance to be back at work within 1–1½ years, instead of his needing extensive surgical treatment on admission to sanatorium and being off work 2–2½ years.

If the conditions laid down by Dr. Toussaint at recent British Tuberculosis Association meeting Liverpool, when he spoke about domiciliary therapy, are adhered to, there is no reason why a p should not progress as well at home as in a sana but the chest physician must have facilities for the term admission of patients for adhesion section, crush, &c. I fully agree with Dr. Temple Clive that short-circuit sanatorium treatment is wrong, but not, he says, "disastrous." The length of the waiting-list is disastrous, and any measure that the physician can take to make this smaller is to the b of everyone. Unfortunately Dr. Temple Clive does the patients whose disease is rendered quiescent by treatment before they are ever offered a bed in sanatorium.

With regard to streptomycin, it will not be possible most cases for this to be given at home, owing to frequency of the injections. Para-aminosalicyclic however, can be given at home; and as the bacillus apparently does not develop a resistance to drug, if a patient has the type of disease which benefit from it there seems to be no reason why it be withheld.

There is no reason why the sanatorium physic should be misled about a patient's progress before admission, whatever the previous treatment, if there is liaison and close coöperation between the sanatorium physician and the chest-clinic physician.

Greenwich Chest Clinic,
London, S.E.10.
C. W. L. JEANES
Chest Physician

SPURIOUS TITLES

SIR,—We earnestly hope that no consultant of full specialist status would agree to employment not in accord with that status. In the clinical field this can have but one meaning—the fullest clinical freedom, full individual responsibility for the care of the patient, and direct relationship between the consultant and the patient's medical advisors, relatives, and friends.

It is therefore with some misgiving that we notice the gradual intrusion of more and more heads, chiefs, directors, and organisers; and more recently advertisements have appeared, inviting more than one consultant to serve a group, area, team, unit, or collection of clinical material or beds, in which we find references to such terms as senior and assistant, bracketed in small letters, apologetically following the title of the consultant. There is no mention of these distinctions in the Act, and if they are to be given a cash value this should be openly stated. The value might really be in undisclosed kind.

This sort of jobbing is distasteful to all but the inefficient, and never in the past has a consultant reached the age at which it is now possible to reach the grade under consideration and still had to look behind him. This is unnecessarily cruel, for these heights are the most vertiginous. Let us hope that this is not really the state of affairs now.

The length of a doctor's professional life as a consultant will be less than 30 years on the average. Let us conside the position if grouping into two, for example, is allowed to take place. Assuming equal ability, the higher consultant should be at least 15 years ahead of the lower. Assuming greater ability, it will take some years for this to become evident and also generally accepted. It seems therefore that if such undesirable and unreal distinctions are allowed to be perpetuated there should be at least 15 years between the consultants, except where undoubted and generally accepted greater ability exists.

The titles of head, chief, director, and organiser are distasteful, if not comical, to the great majority of doctors, and are entirely superfluous. The claim that they administratively economical is the reverse of the fact.

of that night." which he later described with -teristic self-effacement in our Peripatetic columns ii, 625).

ides his appointment at St. Thomas's, Cassidy hysician to the Lord Mayor Treloar Cripples' tal at Alton, the King Edward VII Sanatorium at ırst, and the Children's Heart Hospital at West ıam. For many years he was physician and chief al officer to the Metropolitan Police. In 1913 s elected fellow of the Royal College of Physicians ndon. *The following year he was Goulstonian* er; he later held office as senior censor, and in s Harveian orator. He was also a former president Royal Society of Medicine and of the Cardiac y. He had examined for the universities of Cam-, London, Edinburgh, and Manchester, and for the int Board.

1929 Cassidy was appointed C.B., and the following he became physician to H.M. Household. Two later he received the appointment of physician ng George V, a position which he also held in the of Edward VIII and George VI. After His Majesty's, earlier this year Sir Maurice, who had been nted K.C.V.O. in 1934, was promoted G.C.V.O. ppily, he was injured in a motor accident (in which Cassidy was *also* hurt) and he never *fully* recovered his severe injuries. On Oct. 10 the King visited t his London home to confer on him his new honour.

olleague adds: "It might have been thought from tionality that Cassidy would be genial, but I think re appropriate word is kindly; and yet it is no eration to say that his patients loved him. Some e found him difficult to approach and perhaps austere, but those of us who worked as his juniors house-officers realised how much interest he took eir careers and how helpful he was in the back-d. In our profession a man's success is not estimated ly by the honours he receives but rather by the way consulted by his colleagues, and I know that a proportion of Cassidy's earning time was spent in ing doctors *and their families about* their health. is final illness, which was not due to his accident, owed outstanding courage."

his home life C. M. P. writes: "Except when on tion Maurice Cassidy immersed himself in his ssional life to an exceptional degree, often enough ing seven days in the week. His holidays were care-planned and usually took him far north for fishing eer-stalking. He was then the most delightful anion, capable of remarkable endurance on river ll, cheerful under the most adverse conditions, and d with a happy faculty of seeing the humorous side itty failures and discomforts. He was indeed a good panion as well as a great physician. His married vas a happy one; Lady Cassidy coöperated to the in all his activities, and in their charming home ed herself an ideal hostess.

Cassidy was not attracted by the power and prestige h may derive from high office, nor did he take an e part in what may be termed medical politics, ough his wide contacts and broad sympathies would qualified him for those spheres. In general it was nterest in and devotion to his patients, of all ranks, dominated his professional life. Though he was ly 70 at the time of his death, till his accident had been in full career and seemed in excellent th and there were many who still relied on the help advice he gave so freely and generously."

r Maurice Cassidy married in 1918 Miss Elsie Relfe. re were no children of the marriage.

ROBERT SEVESTRE

M.A., M.D. CAMB.

r. Sevestre, consulting physician to the Royal ester Infirmary, died at his home in Leicester on . 13, at the age of 81.

orn in Calcutta, of Huguenot stock, he was brought England in childhood, and was educated at Rugby ool, Cambridge, and St. Bartholomew's Hospital. qualified in 1893, and some five years later was ointed assistant physician to Leicester Royal Infirm-, later becoming full physician. During the 1914–18 war he served in France in the R.A.M.C., with the rank of major, and was physician to a general hospital. On his return to this country he was on the staff of the 5th Northern General Hospital, Leicester. He was the joint author of the chapter on wounds of the chest in the *Manual of War Surgery*.

Dr. Sevestre held many offices as a citizen of Leicester. In 1929 he was appointed a justice of the peace, and he was also a governor of the Wyggeston Hospital, chairman of the pensions committee, and a trustee of Simons Charity. R. McD. C. writes: "Though of a quiet and retiring disposition, Dr. Sevestre was widely known and highly thought of in the city to which he devoted a full life of medical service. By his passing, a link with the previous generation of physicians has been severed. His work at the Royal Infirmary, to which he unselfishly devoted himself for so long a period, earned for him the gratitude of countless patients."

Mrs. Sevestre died in 1937, and their only son was killed in an accident while serving in the Far East in 1943.

JAMES KYLE

M.R.C.S.

Air Commodore James Kyle, who died on Oct. 8 at the age of 60, was educated at Shrewsbury and Guy's Hospital. A keen Territorial as a student, he was adjutant of the Artist Rifles at the outbreak of the first world war. Although he was in his final year, he insisted on accompanying the battalion to France, serving there until 1916, when he returned to Guy's to qualify in 1918.

After a term as assistant medical officer at Lambeth Hospital, he entered the medical branch of the Royal Air Force in 1919. "Here," writes a colleague, "his military experience and flair for administration proved of great value during the growing pains of a new service, and lucky was the P.M.O. who had Jimmy to lean on; his wise counsel, tempered with humanity and abundant common sense, made him a fine medical staff officer. Later he proved an ideal commandant of the medical training depot: the thousands of medical officers and orderlies who passed through it found in him a wise counsellor and a friend in need. He was a keen shot, and his trim soldierly figure with a gun under his arm and his Labrador bitch at his heels was a familiar sight amidst the wooded Chiltern hills he loved so well. A coronary thrombosis in 1938 curtailed his activities; tournament tennis was, alas, a thing of the past, but he still was able to enjoy a day with the rod or the gun." He remained commandant of the medical training depot throughout the late war. After retiring from the R.A.F. in 1945 he became assistant director of medical services of the British Overseas Airways Corporation, and worked under his old chiefs, Air Vice-Marshal Sir William Tyrrell and, later, Air Marshal Sir Harold Whittingham. He served on the council of the British Medical Association as a Service representative.

He leaves a wife and two daughters.

by reason of poverty or other domestic or personal ties. Adequate remuneration of registrars and consultants now throws the gates wide open everywhere and the whole position is changed. In future, posts (not individuals) should be graded for distinction, and, with as little delay as possible, a suitable authority should be established to determine their status and distribution between hospitals and relieve the Awards Committee of its impossible and unpleasant work.

Birmingham. A. P. THOMSON.

VENTRICULAR FIBRILLATION

SIR,—The electrocardiogram published by Dr. Priest (Oct. 15) shows no convincing evidence of ventricular fibrillation. The record is reproduced in small size, but it seems apparent from it that the condition Dr. Priest has recorded is paroxysmal ventricular tachycardia, for one definite feature is the absolute regularity of the aberrant complexes; in ventricular fibrillation there is always quite marked irregularity. Paroxysmal ventricular tachycardia is not uncommon early in cardiac infarction. I have myself seen several such cases, some proceeding to complete recovery.

London, W.1. DOUGLAS ROBERTSON.

THE REGISTRAR

SIR,—I wish to endorse very strongly the point made last week by "Senior Registrar." I, too, am in that grade and the same problem has concerned me for some time. At my request, the point was raised some months ago before the Central Consultants and Specialists Committee of the B.M.A. The figures then given were that the ratio of consultants to senior registrars to registrars to junior registrars should be 30 to 4 to 2 to 1, not allowing for wastage. These figures were, of course, based on the time for which the post is expected to be held. More recently I have been told that the actuarial expectation of service for a consultant is only 25 years. The wastage factor is very difficult to assess, but, in the interests of economy and fairness, I think that at least two-thirds of those appointed to senior-registrar posts should be able to expect consultant posts. The wastage of registrars and junior registrars will probably be considerably greater. On the basis of these figures the ratio of consultants to senior registrars should be 25 to 6, or, roughly, 4 to 1. I should be interested to hear of any region in which this ratio is attained.

It may interest registrars to know that in at least one region the difficulties and unfairness of the present position are fully appreciated by the secretary and the consultant staff of the teaching hospital. In that hospital steps are being taken to see that the number of registrars in training at any one time is not much greater than the number for which the region will be able to find consultant posts. To this end, the establishment of consultants in the teaching hospital has been increased while that of registrars has been diminished. Is it too much to hope that the staffs of other teaching hospitals and the establishment committees of the regional hospital boards will follow this example?

ANOTHER SENIOR REGISTRAR.

CORRECTION OF MEDICAL REGISTER

The Registrar of the General Medical Council writes:

"I am desired by the Returning Officer to say that voting papers for the purpose of the forthcoming election of one member of the General Medical Council to represent the registered medical practitioners resident in England will be issued on Oct. 25 to all

in England; and tha

be glad if any such practitioner who has not received a voting paper would communicate immediately with the office of the Council (44, Hallam Street, London, W.1), whether or not he proposes to vote in the election, in order to ascertain that his address is correctly entered in the Medical Register."

Obituary

MAURICE ALAN CASSIDY

G.C.V.O., C.B., M.A., M.D. Camb., F.R.C.P.

Sir Maurice Cassidy, physician to the King and ing physician to St. Thomas's Hospital, died at his in London on Oct. 22.

Born on Feb. 29, 1880, he was the son of Dr. Cassidy, C.B.E., who for fifty years was supe of Lancaster Mental Hospital. He received his education in Lancaster and then went up to College, Cambridge, where he took a first-cl both parts of the natural sciences tripos. In qualified from St. Thomas's Hospital, and during next five years he held resident appointments there, including those of medical registrar and demonstrator in physiology. In 1911 he was appointed physician to outpatients, with charge of the electrocardiographic department. While still a house-physician he had held the Salter research fellowship, and he held it again in the two years following his appointment to the staff. Before he joined the staff of St. Thomas's he had the choice of returning to Cambridge, for Clare College had offered him a fellowship. His association with his old college was happily renewed when a few months ago he was elected to an honorary fellowship there.

In the first world war Cassidy served during the early years as physician at No. 2 Anglo-Belgian hospital at Calais, but in 1916 he was invalided home pulmonary tuberculosis, and it was two years before was able to return to work. Later he himself ackno ledged how much his experience as a patient had him as a doctor. L. B. C. writes: "For me Cas was an outstanding physician, not because of his profo knowledge of medicine but because he seemed to k instinctively what each patient needed. He was ne carried away by fads and fancies, or by the mechan of modern medicine. His kindliness, charm, and c mon sense gave confidence to the most diverse peo After a consultation his patients came away impr by him as a man and satisfied that he had done utmost for them. Although cardiology became more more his main interest, he never ceased to be fu mentally a general physician, and in this he excell He represented all that was best in consulting medici To his juniors he was so friendly and unassuming th they forgot his distinction in the pleasure of talk to him. He stood out among his fellows not because any single achievement but for general poise and balan modesty, and humanity. Such men are rare."

Although he had an extensive consultant practi his work at St. Thomas's always came first, and he wo never cut his rounds. A first-rate teacher, he insis that his beds should have a large proportion of no cardiological cases, and his bedside instruction conce trated on the principles of medicine and on the essentials treatment. He kept himself up to date by wide readin and he had the gift of extracting from the literature the things that really matter. As a committee man he was admittedly not at his best, for "he was able to see both sides of a question, and so he was not always decisive in his final opinion." After his nominal retire ment in 1930 he volunteered to come back to St. Thomas's and during the whole of the war years he set an to the younger members of the staff by the way always turned up to rounds even when they entailed journey of forty miles into the country. During blitz he took his share of night duty at the hospit he soon arrived when the major damage was done to building and was "extraordinarily helpful in the th-east Scotland and Northumberland. Northern Ireland it of the question because of war-time difficulties in ort. The harvesters had to be taught to identify the which are polymorphic. This field work proceeded r side with an extensive laboratory study of the botany omy, anatomy, and ecology) of the weeds, and with al experiments in the production of agar. The whole which is also part of the wonderful story of penicillin. t fascinating and bears out once more the old adage necessity being the mother of invention.

G.M.C. ELECTION

RE is a vacancy on the General Medical Council for a representative of the medical profession in England. llowing have offered themselves as candidates :

Postgraduate courses for those studying the special practice of obstetrics and gynæcology will be held at the college, 58, Queen Anne Street, London, W.1, on Nov. 4 and 5, and on Nov. 18 and 19.

Institute of Laryngology and Otology

On Friday, Nov. 18, at 4.30 P.M., Prof. Geoffrey Jefferson, F.R.S., will deliver the annual address at the institute, 330, Gray's Inn Road, London, W.C.1. He is to speak on the Acoustic Neuromas.

British Psycho-Analytical Society

On Wednesday, Nov. 30, at 8 P.M., at 1, Wimpole Street, London, W.1, Prof. Arnold Toynbee, LITT.D., will speak to this society on Poetical Truth and Scientific Truth in the Light of History.

Notes and News

PAYMENT OF REGISTRARS IN TEACHING HOSPITALS

We have already referred[1] to criticism of the arrangement by which registrars in teaching hospitals are "appointed and paid by boards of governors." Representations have been made to the Minister of Health that certain medical schools would prefer to contribute to the salaries of registrars employed in teaching hospitals. This matter has been discussed with the University Grants Committee, who have confirmed the following resolution by their medical advisory committee: "That the committee do not regard it as generally essential, on educational grounds, that universities should contribute to the salaries of registrars employed in teaching hospitals. They would, however, consider it appropriate that any university which desired to make such a contribution up to 50% of the registrars' salaries should be permitted to do so if their financial circumstances allow."

The Minister is prepared to make whatever arrangements may be preferred by a particular university or medical school for contributions towards registrars' salaries. It is not suggested that any initiative should be taken by a board of governors to obtain contributions; but, should a university or medical school intimate to the board that it wishes to contribute an amount of up to half of the salaries of registrars employed in a teaching hospital, the board should agree.

LIMB TEMPERATURE

At a meeting of the Heberden Society in London on Oct. 7, Dr. L. G. C. Pugh spoke on Temperature Gradients and Blood-flow in the Limbs. He began by saying that for over thirty years, since the time of Lefèvre, the idea had been prevalent that all tissues deep to the skin were maintained at a constant temperature of about 37°C; but this idea was no longer acceptable. The temperature varied considerably in different regions of the body. Among the factors determining the local temperature was the surface/volume ratio: large limb-segments, such as the thigh, had different temperature-gradients from smaller segments, such as the arm. In the resting subject, about 70% of the body-heat was produced in the liver and intestines, and only 15% in the muscles. This had been established by measuring blood-flow to the liver and intestines and the temperature-difference between hepatic venous blood and right ventricular blood. Total heat-production in the resting muscle had been calculated from the oxygen consumption of resting forearm muscle. During exercise the main site of heat-production shifted from the centre to the periphery—a fact that might prove important in connexion with the differences in cold tolerance between fat and thin people. The history of channel-swimming showed that some stout people were able to remain long in the water; thin people, on the other hand, were usually unable to tolerate immersion in water of this temperature for more than half an hour. It might be supposed that in subjects with little subcutaneous tissue, muscle-heat was drained away at the site of its production; whereas in people with a relatively thick layer of subcutaneous fat the heat generated in the muscles was available for maintaining general body-temperature. Discussing the effect of local cold on tissue-temperature and blood-flow, Dr. Pugh showed that within twenty minutes of immersing the forearm in water at 17°C the deep muscles cooled from 35° to less than 25°C, and the forearm blood-flow fell from 3·5 ml. per 100 g. tissue per minute to less than 1 ml. He showed, too, that the blood-flow was not significantly increased by sympathetic-nerve block; it was fairly well established, he added, that the blood-vessels were directly sensitive to cold and constricted independently of impulses from the autonomic nervous system.

HISTORY IN THE MAKING

The medical historians of the late war took time by the forelock, and as early as 1941 many of them were at work collecting material for the volumes which are now taking shape.[2] In this country Sir Arthur MacNalty was appointed editor-in-chief of our official history in July, 1941. In the United States compilation of the history is the responsibility of the Federal government, and Colonel J. H. McNinch, director of the historical division of the office of the Surgeon-General, has been appointed editor-in-chief. The U.S. Navy is undertaking its own history under the editorship of Captain Louis H. Roddis. The Commonwealth Dr. Allan S. Walker (Australia), Lieut.-Colonel W. R. (Canada), Dr. T. D. M. Stout (New Zealand), Lieut. B. L. Raina (India and Pakistan), and Colonel C. C. P. (South Africa). As our armies joined forces during the so *our historians are now joining forces in describing* was learnt. Meetings between the editors of the C wealth and the United States were held at Ottawa in and at Oxford in 1948, and a third meeting took month in Canberra.

A FOLLOW-UP STUDY OF POTT'S DISEASE

At the Martina Hansen Hospital in Norway, Dr Alvik [1] has lately undertaken a follow-up study of 507 treated for tuberculous spondylitis between 1936 and Of those who were operated on and who were alive than two years 78·7% were fully fit for work, with 62·3% among those who had been treated tively. These figures are not, however, exactly since the two groups differed somewhat in age and The patients who underwent operation returned to work sooner than those who did not. The commonest of diminished capacity for work was back symptoms ciated with activity or exacerbation of tuberculosis; new destructive process in the spine was detected discharge in as great a proportion as 19%. The proved much better with involvement of the lumbosacral spine than with involvement of the lumbar spine or with multiple foci. Until quite tuberculosis of bones and joints has been regarded as a disease of childhood; but in Norway this no longer good. In the ten years up to the end of 1945 the M Hansen Hospital admitted 1116 patients with tubercul the bones and joints; and only 172 (16·4%) were und age of 15 years. Dr. Alvik sugge of tuberculosis of the bones and of the declining tuberculosis infection-rate.

AGAR

Agar is an unrivalled medium for growing bacteri moulds; without it the war-time production of pen would have been much hampered. It is also used in med as petroleum-agar, to promote peristalsis, without che irritation of the bowel, by resisting digestion, attracting to itself, and swelling to several times its original bulk. used in the preparation of food by Asiatics, to add bulk special diets of diabetics, and in the canning industry prevent the acids of fruit juices from attacking the It is used in the manufacture of soaps, cosmetics, marine storage-batteries, textiles, leather, electric plywood, films, nicotine sprays, paper, &c.; and in diverse industries as electroplating and agriculture. 1939 agar was imported from Japan, where for had been prepared from red seaweed; and when war out it became imperative to produce agar in this co to find a substitute for it. The requisite research results are described fully in a new book.[2] Germany, same quandary as ourselves, apparently did no re obtain new supplies of agar but, to keep existing sto salvaged used agar.

Red seaweed grows in shallow water near low spring tides, or a little deeper, and consequently harvested only on limited occasions and by people acc to boatwork. When war broke out the researchers discover the habitats of red seaweeds off our co Ireland at least two kinds of red seaweed have long used to produce "Carrageen moss," which makes, with a greyish-white blancmange with a delicate flavour a firm reputation as a "food" for invalids. That was all we know about red seaweeds in this country in Otherwise we started from scratch, and had first of all to their habitats and test which of them could be u making agar. Naturally the two species used for Carrageen moss were tried first, and they proved Next we had to find out the best seasons for harvesting mapping included the discovery of whether the reg seaweeds were accessible to the harvesters or not. M the areas were found off our west coast, but a few were

In the United States compilation of the history is the responsibility of the Federal government, and Colonel J. H. McNinch, director of the historical division of the office of the Surgeon-General, has been appointed editor-in-chief. The U.S. Navy is undertaking its own history under the editorship of Captain Louis H. Roddis. The Commonwealth ed Dr. Allan S. Walker (Australia), Lieut.-Colonel W. R. (Canada), Dr. T. D. M. Stout (New Zealand), Lieut.-C B. L. Raina (India and Pakistan), and Colonel C. C. P (South Africa). As our armies joined forces during the so our historians are now joining forces in describing was learnt. Meetings between the editors of the C wealth and the United States were held at Ottawa in and at Oxford in 1948, and a third meeting took pl month in Canberra.

A FOLLOW-UP STUDY OF POTT'S DISEASE

At the Martina Hansen Hospital in Norway, Dr. Alvik[1] has lately undertaken a follow-up study of 507 treated for tuberculous spondylitis between 1936 and Of those who were operated on and who were alive than two years 78·7% were fully fit for work, with 62·3% among those who had been treated tively. These figures are not, however, exactly comp since the two groups differed somewhat in age and The patients who underwent operation returned to full work sooner than those who did not. The commonest of diminished capacity for work was back symptoms un ciated with activity or exacerbation of tuberculosis; b new destructive process in the spine was detected discharge in as great a proportion as 19%. The pro proved much better with involvement of the lumbar lumbosacral spine than with involvement of the tho lumbar spine or with multiple foci. Until quite tuberculosis of bones and joints has been regarded as a disease of childhood; but in Norway this no longer good. In the ten years up to the end of 1945 the Hansen Hospital admitted 1116 patients with tube the bones and joints; and only 172 (16·4%) were age of 15 years. Dr. Alvik suggests that the declining frequ of tuberculosis of the bones and joints in childhood is a refle of the declining tuberculosis infection-rate.

AGAR

Agar is an unrivalled medium for growing bacteria moulds; without it the war-time production of peni would have been much hampered. It is also used in med as petroleum-agar, to promote peristalsis, without che irritation of the bowel, by resisting digestion, attracting w to itself, and swelling to several times its original bulk. used in the preparation of food by Asiatics, to add bulk to special diets of diabetics, and in the canning industry prevent the acids of fruit juices from attacking the m It is used in the manufacture of soaps, cosmetics, lo marine storage-batteries, textiles, leather, electric plywood, films, nicotine sprays, paper, &c.; and in diverse industries as electroplating and agriculture. Be 1939 agar was imported from Japan, where for centu had been prepared from red seaweed; and when war b out it became imperative to produce agar in this coun to find a substitute for it. The requisite research an results are described fully in a new book.[2] Germany, in same quandary as ourselves, apparently did no resear obtain new supplies of agar but, to keep existing stocks salvaged used agar.

Red seaweed grows in shallow water near low-wate spring tides, or a little deeper, and consequently ca harvested only on limited occasions and by people accusto to boatwork. When war broke out the researchers ha discover the habitats of red seaweeds off our coasts. Ireland at least two kinds of red seaweed have long used to produce "Carrageen moss," which makes, with a greyish-white blancmange with a delicate flavour and a firm reputation as a "food" for invalids. That was al all we knew about red seaweeds in this country in 1 Otherwise we started from scratch, and had first of all to their habitats and test which of them could be used making agar. Naturally the two species used for ma Carrageen moss were tried first, and they proved Next we had to find out the best seasons for harvesting. mapping included the discovery of whether the seaweeds were accessible to the harvesters or not. the areas were found off our west coast, but a few were

HE SIGNIFICANCE OF FUNCTIONAL DIFFERENTIATION IN MAMMARY TUMOURS *

B. D. PULLINGER
M.D. Lond.

s as an interpreter of pathological structure that to honour Kettle's memory today. His teaching ork were never limited to the descriptive field. ys ask yourself," he used to say, "where has come from, why and how, and where is it going The only logical outcome of this attitude, which ded the observational phase of pathology of a generation, was to explore disease processes mentally. It was Kettle's great regret that the stances of his life and day prevented the devotion whole time to experimental pathology. Were he ng man now, the obstructions and lack of oppor- would be little less; yet it is clear that to advance nowledge of pathology we shall have to adopt mental methods, desert our pigeon-holes, and nise with the basic sciences as he did in the short nd span of life allowed him.

s therefore fitting to recall Kettle's teaching with ount of what may be learnt from an experimental of functional differentiation in the mammary and its tumours.

INFLUENCING DIFFERENTIATION

ad never given the origin of differentiation in urs very much thought. As a diagnostic aid, enabling o name a primary growth, it is of course invaluable. nd that I was content to accept the fact of functional entiation in tumour cells as an inherent potentiality, gh not always realised, of the diseased as it is of al cells. I must add that this superficial attitude is t all general among pathologists: others with whom e discussed the matter have anticipated some of the sions reached by experiment, on the basis of evelopmental work on amphibia.

the course of some inquiries into the local conditions ring the incidence of hereditary mammary tumours ice, the need arose to vary the degree of functional differentiation at will. This led to a quantitative study of differentiation in the period around puberty.

The mammary gland is one of the few mammalian organs which are still rudimentary at birth, so that, if one knows how to arrest its normal growth and then to continue it by artificial means, one may study development both qualitatively and quantitatively. It is known that the gland will fail to evolve if ovarian hormones are withheld, as by excision of the ovaries, until sometimes in compensation after a considerable lapse of time in the mouse, œstrogen may again be elaborated in the suprarenals. Œstrogens, whether naturally occurring or artificially applied to most spayed mice, cause only outgrowth and branching of the mammary ducts. Progesterone, in combination with œstrogens, but not alone, induces lobular-alveolar or acinar differentiation. There exists a tacit assumption that dosage and response to these hormones are probably related quantitatively because response is so greatly increased with rise in hormone output in pregnancy.

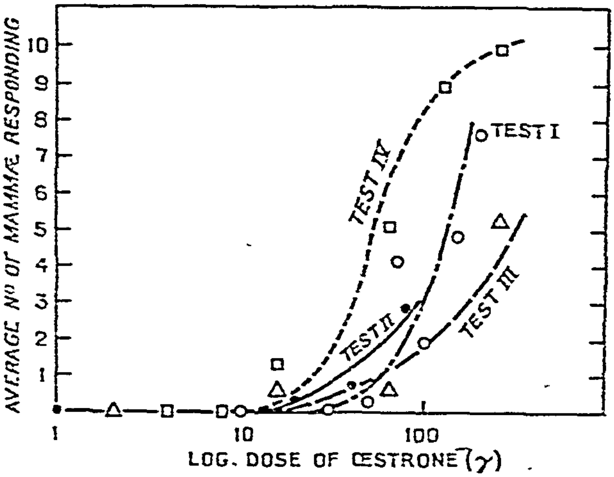

Fig. 2—Relation between dosage and secretion.

A few not very successful attempts have been made to define this quantitative relationship. A satisfactory solution is complicated by the need to measure simultaneously the effect of two substances, one a primary stimulator, the other a synergist. Previously stock mice, whose reactivity was probably far from homogeneous, were the test animals (Mixner and Turner 1943). Attempts may be simplified by using certain inbred strains of mice whose mammæ respond to œstrogen alone with duct outgrowth, acinar differentiation, and secretion. Using mice from an œstrogen-sensitive inbred strain of this kind (Pullinger 1947) I was able, with the indispensable help of my former colleague, Dr. C. C. Spicer, to prove on a statistical basis that a quantitative relationship exists between dosage and response. The precise relationship has been variable from one assay to another, revealing a changing sensitivity, the source of which has not been determined. There remain also practical and theoretical difficulties in such an assay. Nevertheless there is little doubt, as will be seen from figs. 1 and 2, that a true quantitative response exists between dosage and acinar differentiation and between dosage and secretion. A response by secretion in 50% of mammæ was not obtained in any one of the four assays with less than 10 γ œstrone.

MAMMARY STIMULANTS

So far as is known, the mammary gland grows and develops in response to comparatively few stimuli. If the

ttle memorial lecture delivered on Oct. 7 in London.

Guild of Hospital Librarians

A conference on the Hospital Librarian in the Children's Ward is to be held at Chaucer House, Malet Place, W.C.1, on Wednesday, Nov. 9, at 2.30 P.M.

Victor Horsley Lecture

On Thursday, Dec. 8, at 5 P.M., at University College Hospital Medical School, London, W.C.1, Sir Hugh Cairns will deliver the Victor Horsley lecture. He is to speak on Disturbances of Consciousness with Disorders of the Brain Stem.

The Scientific Film Association

A symposium on Problems in Making Psychological Films will be held at the Wellcome *Foundation Institute*, 183, Euston Road, London, N.W.1, on Wednesday, Nov. 16, at 7 P.M. Tickets may be had from the association at 4, Great Russell Street, W.C.1.

National Association for Mental Health

An *inter-clinic conference* will be held on Saturday, Dec. 3, at Queen Mary Hall, Y.W.C.A. Central Club, Great Russell Street, London, W.C.1, for the professional staff of child-guidance teams. Applications should be sent to the conference secretary, at 39, Queen Anne Street, W.1.

Exhibition of Medical Photography

Members of the medical group of the Royal Photographic Society are holding an exhibition in the faculty room of the Bristol Royal Infirmary from Oct. 31 to Nov. 12, from 10 A.M. to 5 P.M. (Saturdays 10 A.M. to 1 P.M.). This exhibition was shown in July in London (see *Lancet*, July 9, p. 65).

South-East Metropolitan Regional Tuberculosis Society

A meeting of this society will be held at Grove Park Hospital, Marvels Lane, Lee, S.E.12, on Saturday, Nov. 12, at 10.30 A.M., when papers will be read by Dr. M. M. Nagley, Dr. Geoffrey Beven, and Mr. Alistair Gunn. There will also be a demonstration of mass miniature-radiography films.

Manchester Royal Infirmary Old Residents' Club

It is proposed to hold the 10th reunion dinner of this club on March 25 at Belle Vue, Manchester. Members will be sent further details early in December, and any former resident whose name may have been overlooked on a previous occasion is asked to write to the honorary secretary, Dr. O. Janus, at the Infirmary.

Diets for Patients with Steatorrhœa

The Ministry of Food announces that patients suffering from acute or convalescent steatorrhœa (including cœliac disease and tropical sprue) who are entitled to half-cream National Dried Milk may, if they wish, take half-cream proprietary infant milk food instead. The maximum allowance remains at one tin a week.

University College Hospital

The annual meeting of the hospital will be held at 5.30 P.M. on Tuesday, Nov. 1, in the medical school, University Street, London, W.C.1, when Major-General Sir Harold Wernher, the chairman of the board of governors, will present the *annual report* of the activities of the hospital including St. Pancras Hospital and the Hospital for Tropical Diseases. Members of the public are invited to attend.

Royal Microscopical Society

On Wednesday, Nov. 2, at 6 P.M., at a meeting of the biological section, Dr. G. A. Harrison, and Mr. M. G. L. Curties, F.R.M.S., will speak on Inexpensive Phase Microscopy. On Wednesday, Nov. 16, at 5.30 P.M., Dr. G. M. Findlay and Mr. F. C. Grigg, F.R.M.S., will address the society on Cytology of the Neurone in Experimental Poliomyelitis. Both meetings will take place at B.M.A. House, Tavistock Square, London, W.C.1.

Postgraduate Travelling Fellowships

The British Postgraduate Medical Federation (University of London) is offering a limited number of these fellowships, tenable for one year, to registered medical practitioners who are at present holding an appointment or are engaged in postgraduate study at one of the undergraduate or postgraduate teaching hospitals or medical schools of the University of London. Further information will be found in our advertisement columns.

Society of Medical Officers of Health

The annual dinner of this society will be held at Piccadilly Hotel, London, W.1, on Thursday, Nov. 7.30 P.M.

Appointments

MITCHELL, J. B., M.D. Lond: asst. chest physician (senior Cambridge area.
MURRAY, R. S., M.D. Belf., F.R.C.S.I., D.M.R.: asst. London Hospital.
PRICE, D. E., M.B. Lond.: consultant pathologist in charge, group of hospitals.
SUTTON, P. H., M.D., B.SC. Lond., M.R.C.P.: asst. chest *(senior registrar), East Norfolk area.*

Colonial Service:

CHEVERTON, R. L., M.R.C.S.: director of medical services, Coast.
MADGE, E. H., M.B. Lond.: medical superintendent, Hospital, Mauritius.
NUNN, J. F., M.B. Birm.: M.O., Federation of Malaya.
ROZALLA, M. A., M.B. Calcutta: M.O., Sarawak.
TONKING, H. D., M.R.C.S.: pathologist, Nigeria.

smallpox to cancer. This is, of course, quite true.
could do the same with chemical substances in
ble amounts from cantharidin to methylcholan-
e. Yet such a comparison of similar properties of
s with specific effects fails to inform one about their
fic differences, which, after all, is what concerns us.
does one virus come to cause necrosis while another
s such a vastly different state of affairs as prolifera-
in apparent perpetuity when grown under favourable
itions of transplantation ?

ese differences may be illustrated by reference to
ox, to herpes simplex, and to the tumour of the
e papilloma virus. Epithelial cells with cytoplasm
et wholly occupied by inclusion bodies of cowpox,
the nucleus displaced and compressed, eventually
nd are lost in a scab. The process could not be
ted and reversed by transplantation. The infected
in herpes, after a preliminary swelling and some-
s nuclear multiplication, gradually undergo lysis,
sce into vesicles, and are lost. The virus in an
tive state may remain in cells that repair the lesion.
ultimate activity is always destructive nor can it be
sted or reversed by transplantation. Contrast this
early or late infection with the Shope papilloma
s. Here the cells have multiplied vigorously to make
rge cell mass ; keratohyalin granules and keratin
e been produced. The surface and aged cells ultimately
but this process can be arrested by autotrans-
ntation of the still living cells which will continue to
r in a new position or even host.

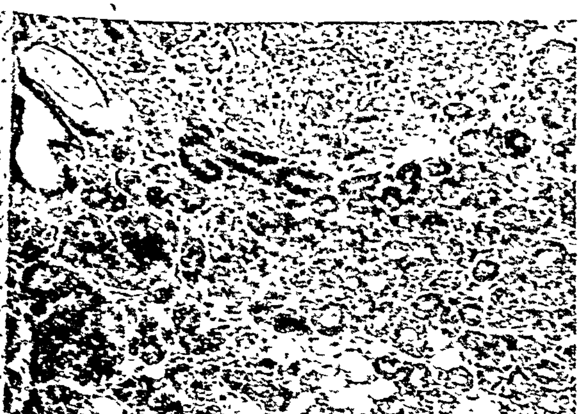
rom the viewpoint of their pathological effects on
s, viruses may more usefully be placed in three groups :

) The *cytoclastic* break up and destroy cells. One may
pose that this effect is due to their production in combina-
with living cells of some substance noxious to the cell,
s brought about by denial, through interference, of some
stance essential to the cell's metabolism.

2) The *symbiotic* live as passengers, neither harming nor
ecting the host cells. Their own metabolism is perhaps
erfect conformity with that of the cells.

3) The *formative* combine with the cells to cause cell
liferation and their own reproduction.

is common sense to suppose that whatever formative
nts do in cells in subserving their own urge to repro-
e is in conformity with the well-being of the infected
ls though not of the host. These viruses may have
ne of the characters of passenger viruses but they
re also something more. In the case of Bittner agents
hereditary mammary tumours, they cause the cells to
ide and to mimic the structural and secretory responses
at only specific stimulants are able to arouse in normal
ls. If one does not assume that the virus, in combina-
n with infected cells, produces a substance having an œstrogen-like property of stimulating cell division, functional differentiation, and secretion, one has to assume that some quite different, perhaps unrelated, chemical entity has these several separate capacities. This second assumption has less to commend it on grounds of Nature's economy. There is also the possibility that both œstrogen and virus excite an intracellular link that effects these changes, a hypothesis that would be extremely difficult to test.



ig. 4.—Mammary tumour showing acinus formation and secretion, four months after the last skin application of œstrone, in a male mouse inoculated with the Bittner agent. (× 150.)

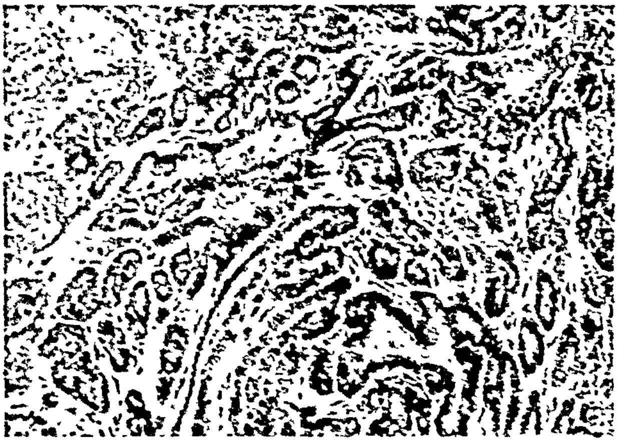


Fig. 5.—Mammary tumour induced with methylcholanthrene (8) in an I.F. strain mouse probably free of the Bittner agent. (× 150.)

THE STIMULUS TO CELL DIVISION

In the earlier days of cancer research it was considered premature to delve into such matters as the probable nature of the stimulus to cell division. Commenting on the subject, W. E. Gye (1925) wrote :

> " The complete failure to provide a unifying conception of the disease has led cancer specialists to look upon the malignant transformation of a cell as a physiological reaction—or a perversion of a physiological reaction—to long-continued irritation. In other words, the disease is regarded as a particular problem in cell physiology and, however clearly external agents may be demonstrated as factors in the chain of causation of tumours their influence is considered to be entirely subsidiary to internal cellular capacities, and particularly to those which relate to cell division. In the final analysis of the pathology of tumours all this may turn out to be true, but as relatively little is known in this branch of physiology, it is premature to indulge in speculation."

That was a quarter of a century ago, and in the meantime endocrinology, a branch of physiology, has provided the key that not only enables one to speculate but also to put that speculation on trial.

The experimental pathologist must be in full accord with the dictum of Peyton Rous that " no explanation of the cause of cancer is worthy of attention that cannot be tested " (Rous and Botsford 1932). Here at any rate is an idea that can be tested, but as yet I do not know whether it is a correct one. The problem is most laborious, technically and I shall show later where the chief exertions lie. First, it is well to consider the relation of the solitary non-virus-containing mammary tumours to the hypothesis that they also are producing intracellularly their own œstrogen-like stimulus to cell division and that they transmit this property in perpetuity. These tumours contain neither an agent which is foreign to the cell nor any clue to the means of cell division. Nevertheless they are morphologically indistinguishable from the multiple virus-containing tumours.

Figs. 4 and 5 illustrate two fields from two comparable tumours of the two origins, one hereditary one induced, both showing differentiation with, here and there, secretion. The one contained the Bittner agent and was transmissible by cell-free extracts ; the other illustration was

TABLE I—CHARACTERISTICS OF MAMMARY CARCINOMAS IN MICE

Type	Agent	Herit-able	Morpho-logy	Rôle of extra-cellular œstrogen	Age incidence
Spontaneous (*a*) Multiple	Bittner's	Yes	Adeno-*carcinoma*	To start and only some-times promote	Young breeders and some virgins
(*b*) Solitary	None found	No	Adeno-carcinoma and squamous carcinoma	To start	Old breeders only
Induced Multiple or solitary	Chemical carcino-gen to start	No	Adeno-squamous, and mixed carcinoma	To start only	Young breeders, virgins, or males

ovaries are removed, only homonymous growth occurs, without elaboration of branches and without functional differentiation. Of the known normal stimuli, œstrogens, both natural and synthetic, are the most vigorous, surpassed only by combination with progesterone. It is thought by some experimenters—and some better evidence has recently been adduced in support of this belief (Jacobsohn 1948)—that a hormone of the anterior pituitary, the mammogen of C. W. Turner and colleagues (Mixner and Turner 1943), also acts as a stimulant and differentiating agent in the mammary gland. Another powerful stimulant, but one that is pathological and usually but not invariably focal in its effects, is the Bittner agent, a virus-like infection of heritable mammary tumours of mice. A third type of powerful focal stimulus, also pathological, the nature of which has so far eluded all search, starts and perpetuates the growth of those mammary tumours, both adenocarcinomas and squamous carcinomas, from which all trace of the Bittner agent is lacking. These growth responses are pathological, giving rise eventually to tumours. Both types, those associated with a virus and those without, occur at isolated foci in the mammary tree. Those in which no agent is found are solitary, those containing the agent multiple. Each has a typical age-incidence. Both differentiate into well-formed acini and evidence of secretion is often found. Their biological characters are thus distinctive—some similar, others quite different, as will be seen in table I.

Both types of adenocarcinomas require ovarian hormone at their initiation, but once they have undergone malignant change they usually grow quite independently of the hormone. My colleague, Dr. Foulds, has found some interesting exceptions among spontaneous and grafted heritable tumours and shown without doubt that they are dependent—though only temporarily—upon ovarian hormone for vigorous growth as distinct from survival (Foulds 1949). The majority, when grafted into males or ovariectomised females, grow as well as ever in the absence of any but undetectable and hypothetical amounts of circulating hormone. The constituent cells are seen in microscopic sections to have been proliferating actively, to have differentiated into acini, and, very often, to have produced secretion also (fig. 3). Since these tumours grow in male and ovariectomised female mice, we may conclude, as indeed we already know, that this cell division, multiplication, functional differentiation, and secretion are independent of ovarian hormone derived from *outside the tumour*. These responses then are inherent potentialities of the tumour cell as they are of the cell of origin.

One is here reminded that, to realise and reveal these inherent potentialities in the normal prototype, one had to provide the competent cell with an adequate stimulus, adequate both qualitatively and quantitatively. Thus it seems highly probable and an economy in assumptions to suppose that the competence of tumour cells to divide, differentiate, and secrete entails also a similar adequate stimulus.

Apart from this similarity in morphological between the differentiated pathological cell and normal œstrogen-stimulated cell, there is no clue *nature of the stimulant*, either to cell division differentiation in these tumours. Thus for the the impulse may be supposed to be a stimulant œstrogen-like properties, or perhaps having a to Turner's "mammogen." All that can be inferred it from other data is that it must be elaborated cellularly and perhaps used and assimilated achieving its end. A few preliminary which an adenocarcinoma was grafted between and 3rd mammæ of some spayed mice failed to differentiation in the neighbouring glands, there is no leakage from dividing and differenti

VIRUS AND HOST

The assumption that mammary tumour producing intracellularly their own stimulus œstrogen-like properties, to divide, differentiate, secrete, must be examined to decide whether or

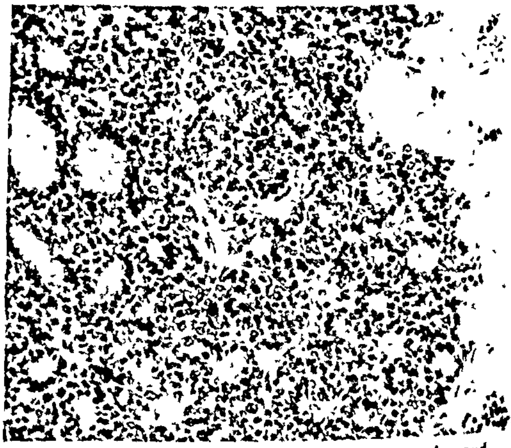

Fig. 3.—Mammary tumour showing acinus formation and an ovariectomised mouse carrying the Bittner agent. (×

conforms with other established data concerning mammary tumours and tumours in general. We that heritable mammary tumours of mice contain Bittner agent, a virus-like entity upon which depend for their spontaneous growth and natural mission, though it is less certain that the grafted are ultimately dependent upon the agent. Once it is an economy in assumptions to suppose that Bittner agent is effective because, in combination the living cell, it is able to elaborate some chemical œstrogen-like properties.

E. H. Kettle (1935) recorded his opinion in a delivered at St. Bartholomew's Hospital, and others have said the same before and since, that a parasite were universally accepted *tomorrow* as cause of cancer we should *still be as far as ever* understanding the cancer process." It is the pro province of pathology, including chemical pathology endocrinology, to unmask its magic and mystery. C. Andrewes (1934) conceived the tumour virus as exi in a state of equilibrium with the parasitised cell, lating it to divide but not destroying it, a state in neither destroyed the other. What we really want know is how all this comes about. Andrewes attention to examples of *every type of change* p *in* cells by the action of *a* virus, from pure necrosis pure proliferation, and expressed the opinion that could construct an ordered series of virus lesions extend

EXPERIMENT

liminary work to put these ideas on trial in relation mmary tumours has shown where some of the cal difficulties lie.

he first place, very large quantities of test tumour ial are required, because the hypothetical growth-ning œstrogen-like substance or "mammogen" ly to be present in very small amounts. The source material must be transplantable tumours, because imperative need to do control trials including rative assays. There is a natural temptation to use of abundant human material but it is out of estion to use it in any crucial tests. The largest source of natural œstrogen, the ovary, must be d: and I am informed by my colleague in endo-gy that scepticism must even then remain to ion whether all traces of extracellular œstrogen been excluded. Traces must be deliberately sought r growing a different type of tumour—a sarcoma, xample—in parallel in the same or in alternate ls and putting it through identical trials. That is st of reality in this particular experiment.

ere is, next, the possibility that the intracellular lus is not similar to œstrogen but rather a protein one or "mammogen," and there is one reason st the supposition of an œstrogen-like nature. is the fact that the mammæ of mice are never lated by *extracellular* œstrogen alone (in the absence ttner's agent) to grow beyond the extreme limits of ormal. In rats, however, excess of applied œstrogen cause mammary tumours in some stocks (Dunning . 1947).

ere are also a few examples of excess of histospecific ones causing tumours—for example stimulation of dotropin by œstrone or by direct action of œstrogens ting in testicular growths (Bonser and Robson). The idea put forward, if it is to have a general ication, requires that one proposes a stimulus for y type of malignant cell. Lately, for some students' res, I searched the pathology of repair, regeneration, hyperplasia to find whether there were any chemical tances known to excite cell division. It was an sting experience to realise that, not until one came he histospecific hormonal hyperplasias did one find chemical substances of this nature. Cell division and tiplication occur, as one knows, in many circum-ces and conditions which end with healing or irrita-hyperplasia, but in none of these conditions has imarily stimulating chemical agent been defined. On other hand, the only substances of an identifiable nical nature associated, apparently primarily, with division are (strange to say) effective by their absence. in the healing of simple trauma it is even suggested, a most cogent experimental proof, that the immediate ulus to cell division is cell scarcity (Wigglesworth 7). Stimulation by anoxia after hæmorrhage and at h altitudes results in increase in red blood corpuscles. other effective absence is that of iodine resulting in roid hyperplasia; yet another is hypocalcæmia which nulates parathyroid growth. It is possible, of course, t these are but links in a chain of causation and that owledge of the immediate stimulus is lacking. There also embryologists and others who do not believe at cell division requires extracellular stimuli.

Some ideas for a search for intracellular tumour-cell muli are to be found in table II. Besides mammary enocarcinomas, the best and most readily available owths for test would be the secreting adenocarcinomas the prostate induced by E. S. Horning and testicular umours by Bonser and Robson (1940). The guess that e intracellular stimulants are respectively androgen and onadotropin rests upon known relationships in normal d pathological growth. There is also supporting idence in the case of induced prostatic tumours in the depressing effect on growth of grafts of withdrawal of androgen (Horning 1949): in human spontaneous tumours of the antagonistic action of œstrogens. One may hazard the guess that the reason why œstrogens are not more effective is their inability to affect the source of production of androgen. The product may be rendered partially or even completely ineffective, but the mechanism remains.

TABLE II—SUGGESTIONS FOR THE INTRACELLULAR SELF-STIMULUS OF SOME EXPERIMENTAL TUMOURS

Type of tumour	Heritable intra-cellular stimulus	Detection and assay
Mammary adeno-carcinomas	Œstrogen-like steroid (or anterior pituitary "mammogen")	Mammary response in young spayed females
Prostate adeno-carcinomas	Androgen	Various assays
Testicular carcinomas	Gonadotropin or œstrogen	Testicular response
Thyroid adeno-carcinomas	Thyrotropic hormones	Various assays
Luteomas	Gonadotropin	Luteinising activity
Suprarenal-cortical tumours	Adrenocorticotropin	Repair and maintenance tests
Leukæmias	? Myeloid metaplasia factor in urine	Blood-count

Thus it will be seen that the possibility of testing this theory in relation to tumours in general depends on the fulfilment of four requirements:

(1) a guess must be made, or previous knowledge exist, of the normal histospecific stimulus to division of the cell of origin of the tumour;

(2) extraction of this hypothetical substance from transplantable tumours;

(3) identification and possibly assay accompanied by

(4) all relevant and proper controls duly devised for their reality-testing purpose.

Much depends upon extractability. It is indeed probable that the very stimulants we seek are assimilated into the substance of the cell and so combined that they are not separately extractable.

The first necessity, the guess concerning the chemical nature of the stimulus, is also a source of great difficulty, because of our lack of knowledge of normal stimuli. That same ignorance—so prevalent in pathology—was encountered on inquiring into experimental embryology also. Apparently the great endeavour to determine the nature of evocators ended, one hopes only temporarily, in an embarrassment of non-specific stimuli. So, assuming that Nature is economical in her means and uses similar substances for similar ends, the histospecific hormones alone provide clues for the first experimental trials. They are sufficient and worthy to go on with.

SUMMARY

The convergence of two groups of observations led to the hypothesis that mammary tumour cells produce intracellularly an œstrogen-like substance or "mammogen."

The first set of observations were based on attempts at assessment of the relationship of dosage and response between œstrone and the mammary glands of spayed mice at puberty. Results indicated that lobular-alveolar or acinus formation and secretion depended upon a specific stimulus applied in adequate quantity. In the absence of a specific stimulus there was no response.

The second set of observations concerned the known property of spontaneous mammary carcinomas of mice to differentiate into acini and produce secretion, and to retain these characteristics when grafted into ovariectomised female or male mice. The conclusion was reached that this response also is most probably due to intracellular production of an œstrogen-like substance.

kindly given me by Dr. Dmochowski and Professor Orr, of Professor Passey's department in Leeds. The second tumour was produced in an IF strain mouse by means of methylcholanthrene. This strain, bred originally by Dr. Bonser, is most probably free of Bittner's agent and the tumour itself has been exhaustively tested by every known means for the presence of agent and none was found. Products from it were examined in Leeds by electron microscopy and no particles found; extracts were injected into young susceptible mice, which in later life as breeders failed to develop mammary tumours themselves (Dmochowski and Orr 1949). Nothing, it seems, save the omnipotence of thought can endow either that tumour or many like it with any known virus-like agent. Nevertheless, the morphological characters of the tumour suggest that it also is elaborating an œstrogen-like intracellular stimulus and has the capacity to transmit this property.

The obvious course once again is to put the idea on trial; but, since scientific endeavour is costly in time and money and life is short and restricted, it is worth while taking stock of the position as a whole to see whether the attempt justifies the effort entailed. It will be justified only if the hypothesis of an intracellularly generated self-stimulus to division affords an explanation of tumour growth in general. Four imperative conditions will then have to be met, starting from the assumption, itself open to question, that cell division in multicellular organisms requires some stimulus other than adequate nutrition. This assumption will be contested by microbiologists and by at least some embryologists. Even so, one of the former—A. W. Peters—on the basis of experimental work with Stentor considered that potassium exerted a specific qualitative effect, other than that on osmosis, in exciting cell division (Peters 1904). In respect of tumours in multicellular organisms a working hypothesis must be based on some assumption in respect of the stimulus to cell division. One must believe in and look for either a positive stimulus or else in a removal of an inhibition. I myself look for a positive stimulus, a decision which is arbitrary perhaps and may be wrong. Yet it appears to conform to the need of most living things, for an impulse to call forth activity. Though our ignorance of stimuli to division of somatic cells is very great, the responses to the histospecific hormones are pointers to the existence of actual positive stimuli.

Having then assumed the need for an impulse for cell division:

(1) Provision must be made by the theory for the presence in tumour cells of a specified intracellular self-stimulus to division. (The facts relating to tumour grafting demand that this condition be fulfilled. Grafting of tumour material from animal to animal in successive generations of grafts to which no limit can yet be set proves that the malignant property is inherent in the cells themselves and is conveyed with them from host to host.)

(2) A mechanism must be suggested for the linear transmission of this stimulus in somatic cells.

(3) A plan must be provided for experimental trial.

(4) The plan must be amenable to reality-testing by control experiments.

So far the virus theory, as a theory, has most satisfactorily filled the bill because it provided the self-stimulus to division and also its means of transmission. The virus was the stimulus, though its method of action remained a mystery that has never been inquired into as far as I know. As the cell divided, the virus was passed on and itself multiplied. Where this theory has failed is in deliberate attempts at straightforward trials by planned experiment, duly controlled, except in the general instance of avian sarcomas and also the leopard-frog tumour and Shope papilloma. Otherwise those tumour viruses which are known to us have been found accidentally under exceptional conditions of
The story is too familiar to need repeating.
failure may be due to lack of ingenuity in devising experiments.

A CHANGE IN CELL CHEMISTRY ?

The results of mammary-gland assays and
of mammary tumours growing in male and
female mice have let in a glimmer of
concerning the probable way in which one
Bittner agent—brings about its effects. If it is
that an infecting virus may act in combination
living cells to stimulate cell division and fun
differentiation, then it seems not improbable that
same sort of chemical elaboration in the cell might
about in other ways. It has always been a
of the so-called theory of somatic mutation
merely provided what W. E. Gye and others
as a verbal explanation of what we already know.
said that a heritable change had occurred in
cells. There are many other adverse criticisms of
theory, nor can it be put on trial. If, however, one
aside the old formula and says simply that the
cell has undergone a change in chemical p
so that it has come to elaborate its own stimulus
cell division, then there are certain circumstances
which the theory can be tested. A theory stated in
way may fulfil three out of the four imperatives of
explanation of tumour growth: the first, third,
fourth. It does not account for transmission. Yet
know from the fact of functional differentiation
ontogeny that changes in cell chemistry occur and t
they are thereafter heritable.

In adult cells heritable shifts in chemical pro
are sometimes seen in tumours. It is often a ma
debate whether a change is in a new direction, w
a true metaplasia has occurred rather than rev
to the cell of origin.† Some recent examples of
tumours indicate complete reversibility in either
direction of secretory activity or of keratinisation.
such tumour is that induced in prostatic epithelium
Dr. Horning (1949). It frequently starts as a
secreting adenocarcinoma, but after several ge
of grafting it becomes a keratinised tumour. His fig
is a specially convincing specimen, showing
cells in the interior of an alveolus and squamous
which appear to have arisen directly from them, spre
at the periphery. Here the change in chemical
tivity is from a fluid-containing soluble protein and
lipides to a type of cell which yields only keratin. In
mammary gland mixed adenocarcinomas and squam
carcinomas are often seen in which there appears to
reversibility between cells differentiated to secrete
proteins, fats, and sugar to cells that produce ke
only, and vice versa. Underlying the structural
bility one must suppose a change in chemical prod
tivity, and it does not appear unreasonable or
to suggest that an invisible intracellular chemical stim
to division might also be elaborated and then the capaci
become heritable in somatic cells. In the case of
mary adenocarcinomas it might be an œst
steroid or a "mammogen"; in the prostate an androgen.

The idea is in harmony with that expressed by J. B. S
Haldane (1934). He thought it reasonable to regard carcinogenesis as "anomalous differentiation rather than mutation." The anomaly would consist in a change in intracellular chemistry in the direction of elaborating its own stimulus to division and sometimes also to functional differentiation.

---

† Since this lecture was given I have been reminded that J. A. Murray (3rd Scientific Report of the Imperial Cancer Research Fund, 1908, p. 159), argued in favour of reversibility of growth forms in mammary tumours.

DETAILS OF MANAGEMENT

patient is given 500,000 units of penicillin every -four hours, in divided doses, by intramuscular on.

er infiltration anæsthesia a burr-hole is made over e of the abscess—except when the abscess follows yelitis of the skull, in which case the dura mater sed by the removal of the infected bone, and a l anæsthetic should be employed because of the ce of superficial sepsis. In the region of the posterior a burr-hole is somewhat more difficult to make, to the thickness of the muscles.

nall cut is made in the dura mater; a brain cannula sed into the abscess; and some of the pus is ted. A mixture of penicillin solution and diodone ore than 2–3 ml.) is then injected into the cavity diograms are taken to show the exact position and the abscess. Before the cannula is withdrawn, the ning pus is aspirated and a further quantity of llin solution is injected into the cavity. It is tant that the penicillin should be of the highest , and that the solution should be concentrated 00 units per ml.) so that its volume will not disrupt scess wall.

st authors recommend 'Thorotrast' as an opaque m (Kahn 1939). It has the advantage that it ns in the abscess and enables one to observe action or expansion of the capsule. But there is imental evidence that thorotrast stimulates capsule tion (Falconer et al. 1943) and we prefer a completely bable substance.

casionally an abscess will heal after one penicillin-cement, but usually several replacements will be red, and these can be done with the scalp sutures t. Considerable judgment is needed in deciding the g of the aspirations, and careful attention should id *each day* to the patient's general and neurological . Further replacements should be undertaken on lightest evidence that he is not progressing—e.g., re of the level of consciousness to improve, persisting ache, vomiting, a change in the pulse-rate (either ase or decrease) or failure of the papillœdema and ocalising signs to subside. To begin with, needling be required at intervals of a day or two, but when ress is satisfactory the intervals become longer until ore pus can be obtained. One of the effects of the cillin is to keep the pus thin, thus allowing aspiration e continued. If despite aspiration and penicillin-cement the patient's condition ceases to improve, or riorates, then either the capsule of the abscess is , and is acting as a "tumour," or the abscess is locular. In these circumstances ventriculography ld be carried out and preparation made for the total oval of the abscess. (There is also the possibility of e than one abscess when the thorax is the source of primary infection.)

efore the enucleation is done, penicillin (10,000 units ml. normal saline) is injected into the ventricles ugh one of the burr-holes used for the ventriculo-phy and also by lumbar puncture. An osteoplastic is then made over the site of the abscess; or when is in the posterior fossa a cerebellar exposure is used. dura mater is incised and the abscess exposed by removal of overlying brain tissue. The capsule is n carefully dissected out, and when complete hæmo-sis has been secured penicillin-sulphadimidine powder lusted into the remaining cavity. The wound is closed hout drainage.

When an operation is done for an abscess arising from eglected open fracture, loose fragments of bone and eign bodies are removed. The abscess itself is slowly d gently extracted by suction until a clean-looking vity is obtained. The wound is then closed without ainage. If the scalp is deficient over the fracture one of the usual plastic methods of covering the defect is employed.

A brain abscess may sometimes follow a chronic course, the onset of pressure effects and localising signs being delayed. In these cases the abscess persists as an almost solid mass of fibrous tissue giving rise to a picture indistinguishable from that of a tumour. In such a case total excision is indicated.

A patient with an abscess may develop meningitis; or a patient with meningitis, who is not making satisfactory progress, may be harbouring an abscess, either in the brain or encysted in the subarachnoid space. Thus in cases of meningitis complete and frequent neurological examinations are of great importance. These cases of meningitis associated with an abscess can be treated successfully by chemotherapy with surgery on the principles described above.

TREATMENT OF THE FOCUS OF INFECTION

As the brain abscess constitutes the immediate threat to life, it should be treated surgically before the primary source of infection, except in the case of osteomyelitis of the skull when the diseased bone should be removed during the attack on the abscess. Where the primary lesion is in the lungs it is important that radical surgical treatment should be undertaken as soon as the patient's condition allows; for there is a tendency for further metastatic brain abscesses to form (Pennybacker and Sellors 1948). With otitis there is not the same urgency; but there is no reason to delay mastoidectomy once the intracranial lesion has healed.

CASE-RECORDS

Following these principles we have had only one death in the last eight cases of brain abscess admitted to Oldchurch Hospital, Romford, and the West End Hospital for Nervous Diseases.

Case 1.—*Boy aged 15. Left mastoiditis, meningitis, cerebellar abscess. Treated by aspiration and penicillin-replacement. Recovery.*

The patient was admitted to hospital on Sept. 5, 1945, with a history of a discharging left ear, tenderness behind the ear, headache, photophobia, and neck stiffness. He was diagnosed as having mastoiditis with meningitis. A cortical mastoidectomy was performed and the formerly purulent cerebrospinal fluid (C.S.F.) became normal under penicillin therapy, though his fever never settled completely.

Three weeks later he developed more headache and neck rigidity. Bilateral papillœdema was found and shortly afterwards cerebellar signs were apparent in the left arm. A diagnosis of cerebellar abscess was made, and on Sept. 30 a posterior-fossa decompression was performed and the left cerebellar hemisphere was needled through the dura mater with aspiration of 6 ml. of pus (culture: anaerobic non-hæmolytic streptococci). Two days later he became more drowsy and the abscess was tapped. A further 11 ml. of pus was aspirated and penicillin (20,000 units) was injected into the abscess cavity and along the needle tract. On five occasions during the next twelve days, because of headaches and increasing drowsiness, pus was again aspirated and penicillin injected.

On the next two attempts no pus was aspirated though the brain needle encountered increased resistance. The cerebellar signs had largely cleared, but the boy still had papillœdema, was vomiting, and complained of severe headaches. It was thought that an abscess capsule was causing pressure effects, and on Oct. 27 a further posterior-fossa exploration was carried out and the dura mater was opened. Examination of the left cerebellar hemisphere, however, showed no evidence of any abscess capsule. The abscess appeared to have r solved completely. After this second operation the boy made a steady recovery; he was discharged from hospital on Jan. 9, 1946, and has since remained well, leading a normal life.

This case established the important fact that repeated aspiration of pus, with penicillin-replacement, can cause a brain abscess to resolve so completely that there are no signs of it at operation.

In the case of inherited tumours of mice due to the Bittner agent it is conceivable that the agent in combination with mammary cells is producing some such substance; in the case of agent-free tumours the suggestion is made that a heritable change in chemical productivity has occurred in mammary cells resulting in the production by the cell of its own chemical stimulus to division and differentiation.

The hypothesis is examined in relation to the tumour problem in general and a forecast made of the intracellular impulses of some other types of tumour together with indications for testing its validity.

I am greatly indebted to Dr. C. C. Spicer who undertook the whole of the statistical work. Also to Dr. L. Dmochowski and Prof. J. W. Orr, and to Prof. R. D. Passey for permission to use their material.

THE TREATMENT OF BRAIN ABSCESS

WITH SPECIAL REFERENCE TO A CONSERVATIVE METHOD

LESLIE C. OLIVER
F.R.C.S.
NEUROSURGEON, WEST END HOSPITAL FOR NERVOUS DISEASES, AND ROYAL NORTHERN HOSPITAL, LONDON; SURGEON IN CHARGE OF NEUROSURGICAL CENTRE, OLDCHURCH HOSPITAL, ROMFORD

W. L. B. LEESE
M.A., B.M. Oxfd
RESIDENT MEDICAL OFFICER, WEST END HOSPITAL FOR NERVOUS DISEASES

BEFORE the days of penicillin many of the lessons learned by neurosurgeons in dealing with intracranial tumours had been applied to the management of brain abscess. Penicillin, used in conjunction with sound surgery, has made brain abscess one of the most satisfactory conditions the neurosurgeon is called upon to treat. The essentials are (1) accuracy of diagnosis and localisation, (2) application of the neurosurgical principles governing treatment of a space-occupying lesion, together with those that apply to sepsis, and (3) day-to-day review of the patient's general and neurological state.

Today there are two main schools of thought regarding the treatment of brain abscess. In some centres the abscess is extirpated as soon as it is thought that an adequate capsule will be found (Vincent 1937, 1938, Pennybacker 1948). The formation of such a capsule takes several weeks, during which period aspiration and sometimes decompression will be needed if the patient's condition deteriorates substantially. In other centres, particularly in America (Klemme 1948) and France (Le Beau 1946), the introduction of penicillin has encouraged radical excision of all abscesses as soon as they are diagnosed and preferably before a capsule has had time to form.

The purpose of this article is to recommend a third and more conservative method of treatment—namely aspiration and penicillin-replacement alone—and to reconcile all three methods. But first we shall summarise the causes of abscess.

CAUSES OF BRAIN ABSCESS

1. *Septic Lesions of the Thorax.*—A brain especially liable to follow operations for septic of the lungs and pleura (e.g., lobectomy for and drainage of an empyema). This type of become commoner with the development of surgery. Septic secondary deposits from the bronchus may cause confusion in diagnosis.

2. *Middle-ear and Mastoid Infection.*—An the temporal lobe or the cerebellum may arise infection in the middle ear or mastoid, chronic cases associated with the inflammatory cholesteatoma. The incidence appears to be much as the result of recent advances in chemotherapy.

3. *Infection of the Frontal and Ethmoidal Sinuses.*

4. *Open Injuries of the Skull.*—The regards a fracture of the skull as "open" when the mater has been penetrated. With such an injury, abscess is almost certain to form if fragments of hair, or hat-material have been left in the subs the brain. A bullet is much less likely to be the of an abscess, and damage to vital structures be risked for the sake of its removal. Such cases however, be followed up, for an abscess may arise years after the injury.

5. *Osteomyelitis of the Skull* is usually caused blood-borne *Staphylococcus aureus* but may also fol infection of the nasal sinuses or the scalp. A scalp tion may produce a cerebral abscess without infection of the bone.

6. *Septic Disease Anywhere.*—Examples: osteomyelitis, whitlow, tonsillitis.

7. Where there is *no apparent cause* for abscess, condition is likely to be diagnosed as malignant glio We have seen a case in which the signs of a space o pying lesion developed a few weeks after a closed h injury. A burr-hole was made for the evacuation o suspected subdural hæmatoma, but the subdural sp was clear. The brain was next needled in search of intracerebral hæmatoma, but instead the needle ente a large abscess. No focus of origin for the infection co be found.

BACTERIOLOGY

Organisms isolated from abscesses of the brain incl *Staph. aureus* and *albus*, *Streptococcus pyogenes*, and *pneumoniæ*, *Pseudomonas pyocyanea*, *Proteus vul*, actinomyces, diphtheroids, and *Hæmophilus influenzæ.* some cases a mixed growth of organisms is obtained. is important to determine the nature of the respons organisms and to test their sensitivity to penicillin, sulphonamides, and to streptomycin.

TREATMENT

The methods of treatment now available are:

1. *Delayed excision* after a capsule has had time to life being maintained by delayed penicillin-re and sometimes also by decompression (the dura being left intact). The object is to *encourage* the of a thick capsule.
2. *Immediate radical excision* as soon as the diagnosis made.
3. *Aspiration and penicillin-replacement without exci* begun as soon as the diagnosis is made and when necessary *without delay.*

There is no case for the universal application of an one of these methods, and our scheme of management embodies all three. The aim, however, should be to *discourage* the formation of a thick capsule by means of early and repeated aspiration and penicillin-replacement combined with *adequate intramuscular and intratheca* penicillin. Only if the abscess fails to resolve is it excise An abscess arising from a neglected open comminute fracture of the skull is removed by suction, as soon as is diagnosed.

May 18, 125 ml. of thick pus was aspirated from an ss in the right posterior frontal region and penicillin 0 units) was injected into the cavity. Radiograms taken the injection of iodoxyl showed a unilocular abscess -positive fragments of a branching mycelium were found pus.

er the aspiration the patient was less drowsy, but there o improvement in the paralysis. On May 25, 100 ml. of as aspirated from the abscess and 100,000 units of peni- injected. An aerobic actinomyces was isolated from the Next day the flaccid paralysis had become spastic. On 1, 110 ml. of pus was aspirated and 200,000 units of illin injected. After this aspiration, movement began arm in the left arm and leg. Eight days later only 5 ml. s could be aspirated from the abscess cavity, but the boy nued to improve steadily. By June 21 the papillœdema lisappeared and on July 26 he was walking unaided.

en in May, 1949, he walked normally and had begun to ride all bicycle. He attends school regularly and is doing very there. His mother says he is reluctant to use his left, gh it is as strong as the other.

ectroencephalography (Dr. D. Gordon) in May, 1949, a normal resting record. On overbreathing there was a p of sharp waves in the right frontoparietal region which no counterpart on the left; also there was one high- ice spike with phase reversal in the same area. This is estive of a focus of scarring in the area corresponding e abscess site.

ase 8.—*Man aged 52. Meningitis following a fall. Cere- r abscess. Treated by aspiration and penicillin-replacement. very.*

n Sept. 11, 1948, the patient fell off his bicycle, but ained abrasions only. A week later he developed rigors, lache, and neck stiffness. He was admitted to hospital re the C.S.F. was found to be purulent and grew *Staph. enes.* In spite of intrathecal and parenteral penicillin a course of sulphamezathine by mouth, he became easingly drowsy and developed a left-sided hemiparesis h was more pronounced in the arm than the leg. There also a right ptosis and mild bilateral papillœdema. On . 8 he was transferred to Oldchurch Hospital with a mosis of right frontal lobe abscess following meningitis.

n Oct. 12 the right frontal lobe was needled but no abscess found. A ventriculogram showed symmetrical lateral tricles which were grossly dilated. A burr-hole was made r the posterior fossa on both sides and an abscess was nd in the right cerebellar hemisphere. Several millilitres of k pus (sterile on culture), was aspirated and penicillin ,000 units) was injected into the abscess cavity.

he drowsiness and left-sided weakness improved. On r. 13, however, he became comatose again and the abscess retapped. Pus 7 ml. was aspirated (culture again sterile) penicillin was injected intrathecally, into the ventricles, into the abscess cavity. As his condition improved so ly, the abscess was tapped again on Nov. 19, but no pus was nd. Steady recovery followed and three weeks later he allowed to get up; but there was still weakness in the left er limb, especially at the wrist, and also slight incoordination the left arm. The power in the left leg was normal.

Three months later there was still weakness of the arm ugh walking continued to improve. He started light work June, 1949.

CONCLUSIONS

The delaying tactics required to encourage maturation a *thick* capsule with a view to ablation of an abscess e not without danger; death may occur suddenly m the effects of tentorial or cerebellar herniation, the capsule may rupture into a ventricle. The tient will usually survive the preliminary phase of is treatment, but the risks of removing the tumour" always remain. Neurological signs, either resent at the time of the diagnosis or developing uring the waiting period before enucleation, may not e relieved or may be made worse by the destructive ffects of dissection.

The method of early aspiration and penicillin-replace- ent aims at preventing the formation of a *thick* capsule, o as to obviate the major operation of enucleation. The actors making for success are early diagnosis, immediate leedling (repeated if possible before there are signs of urther expansion of the abscess), and the use of a contrast medium which is unlikely to stimulate capsule formation.

Although, in our experience, no abscess has recurred, there is the danger that resolution may be only apparent. Hence it may be thought advisable to carry out air-studies and other ancillary methods of investigation before the patient is discharged from hospital, and it is essential that all cases should be followed up at short intervals.

The number of patients we have treated by the conservative method is small, but the results justify a continued trial of the technique.

SUMMARY

An account of the causes of brain abscess is followed by a discussion of the present-day methods of treatment.

No single method is applicable to all cases; but the use of aspiration and penicillin-replacement, without excision, reduces the risk to life and function to a minimum, and is recommended for the majority of brain abscesses.

Eight case-records are presented to support the views expressed. In six cases aspiration and penicillin-replacement without excision of the abscess produced a cure, and in two of these cases only one needling was necessary. In the other two cases excision of the abscess could not be avoided.

Continuous spinal or peridural block as a means of treating hypertensive heart-failure has been recognised in the United States for several years. Sarnoff and Farr (1944) used single-dose spinal block in four cases of hypertensive heart-failure. Others (Pitkin and McCormack 1928, Cosgrove et al. 1937, Hingson and Edwards 1943) were impressed with the value of spinal and peridural analgesia for childbirth in patients handicapped by cardiac or respiratory disease. The benefit derived from this method may be attributed to the fall in blood-pressure, which reduces the load on an embarrassed heart—described by Dripps and Comroe (1946) as a "bloodless phlebotomy." The potentialities of spinal and peridural block as a therapeutic measure have been considerably increased by the introduction of continuous methods, associated with the names of Lemmon (1940) and Hingson.

These methods have received little publicity in this country, but the recent visit of Prof. Robert A. Hingson, of Baltimore, to Europe will doubtless stimulate further

Case 2.—*Man aged 33. Lung abscess following osteomyelitis of the femur. Left frontal abscess treated by aspiration and penicillin-replacement. Recovery.*

In 1939 the patient developed osteomyelitis of the right femur, followed by a chronic sinus in the thigh. In March, 1946, he had a hæmoptysis and signs of a lung abscess on the right side. He was admitted to hospital on Sept. 10, 1946, after a series of epileptic fits on the previous day. He had gross motor dysphasia and a right upper-motor-neurone facial weakness. The signs remained stationary until Oct. 15, when the left optic disc showed early papillœdema.

On Oct. 16 the brain was needled in Broca's area and 23 ml. of pus was aspirated from an abscess 3 cm. beneath the cortex. Culture was negative, but a film showed gram-positive cocci. Iodoxyl was used to verify the shape and size of the abscess and 80,000 units of penicillin was injected into the cavity. Two days later 42 ml. of pus was aspirated and a further 80,000 units of penicillin injected. Pus was obtained on four subsequent occasions in the next eight days. On Nov. 9, 1 ml. of iodoxyl was again injected into the cavity and radiography showed it to be much smaller. Two days later no pus was found on aspiration. Meanwhile his dysphasia and facial weakness steadily cleared up, and when he was discharged on Jan. 3, 1947, his speech was normal and his papillœdema had subsided.

On Oct. 11, 1947, he had a generalised epileptic fit, and since then he has had an attack every six months; these are becoming less severe on drug treatment. In March, 1948, he had a right pneumonectomy (Mr. Vernon C. Thompson) because his chest condition was not improving. He is now working a 48-hour week as a carpenter's mate.

Case 3.—*Boy aged 7. Depressed fracture of right frontal bone with cerebral laceration, and right frontal lobe abscess. Treatment by excision in the acute stage. Recovery.*

On Dec. 2, 1946, the patient sustained a head injury with a depressed fracture of the right frontal bone, though he was not rendered unconscious. The scalp wound went septic and he was admitted to Oldchurch Hospital eleven days after the accident because he had then been vomiting for two days. Examination showed an area of depression two inches above the outer canthus of the right eye, and an infected scalp wound was discharging clear fluid. His pulse-rate was 60 per minute, but there were no localising neurological signs.

At operation on Dec. 17 a right frontal scalp flap was elevated and the bone fragments were removed. The dura was found to be lacerated and an infected brain fungus protruded; a large abscess with no apparent capsule extended 3 cm. inwards towards the lateral ventricle. All the abscess material was sucked out until the surrounding brain tissue looked normal. Penicillin-sulphadiazine powder was used in all layers of the wound, which was closed in layers without drainage.

For a few hours after operation the boy was extremely shocked. Subsequently his convalescence was uneventful except that encysted fluid under the scalp flap had to be tapped several times. The bone defect was filled with rib-grafts on April 29, 1947, and he was discharged home three weeks later. In March, 1949 (aged 10), he was reported as very active physically but backward with his lessons (mental age, 7½).

In this case the open depressed fracture and lacerated brain demanded immediate operation, and excision of the abscess was the method of choice.

Case 4.—*Man aged 26. ? Cavernous sinus thrombosis, 1942. Right frontal brain abscess, treated by aspiration and excision, 1947. Death.*

In 1942 the patient collapsed with severe frontal headache. His eyes were puffy and he had many septic spots on his face. He was treated as a case of cavernous sinus thrombosis. Subsequently he developed bouts of frontal headache and swelling of the face which on two occasions (March and July, 1946) were relieved by antrum washouts. In September, 1946, he began to get painful spasms of the neck muscles, and frontal headaches. The condition fluctuated until April, 1947, when he began to be drowsy. Admitted to hospital on April 11, 1947, he was found to have bilateral papillœdema and exophthalmos, greater on the right side. He was thought to have had a recurrence of his cavernous sinus thrombosis, but despite penicillin injections his condition deteriorated and he developed a left facial weakness and a weakness of the left grip. On April 18 he was transferred to Oldchurch Hospital and diagnosed as a case of right frontal abscess.

At operation next day, 6 ml. of pus was aspirated right frontal region; but as it was felt that this pus was insufficient to account for his condition a gram was taken. This showed gross displacement ventricular system to the left. A bone flap was turned down and a large thick-walled abscess, firmly to the cribriform plate, was excised. The patient suddenly six hours after operation and died within Post-mortem and histological examination showed a able extent of *encephalitis posterior to the* abscess. cavernous sinuses appeared normal.

Case 5.—*Man aged 34. Chronic left ear infection, lobe abscess, treated by aspiration and penicillin- Recovery.*

This patient had had a discharging left ear since On May 21, 1947, he had a more profuse discharge headache, vomiting, and neck stiffness. The C.S.F. was to be purulent. He was admitted to Oldchurch May 29, at which time he was drowsy but able to *There was early papillœdema on the left side,* right motor-neurone facial paresis, and marked dysphasia. was also mild intermittent fever. The diagnosis temporal-lobe abscess associated with meningitis.

On May 30 the abscess was needled under local and 12 ml. of pus was aspirated (culture: *Staph. albus*). cillin 125,000 units was injected into the abscess cavity; of diodone was also injected and X-ray pictures showed thin cavity. *After aspiration there was steady* his speech and his headaches were also better. On June as he had some recurrence of his headache, though his was still improving, the temporal lobe was tapped but no evidence of any pus or of a capsule could be An uninterrupted recovery followed.

In October, 1947, a radical mastoidectomy was perf In July, 1949, he was quite fit and there were no signs.

Case 6.—*Woman aged 21. Left temporal abscess, three after dental treatment. Treatment by aspiration and pe replacement. Recovery.*

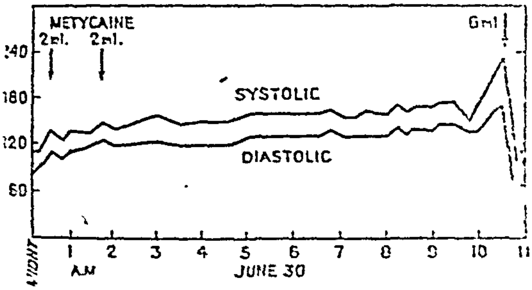
The patient was admitted to hospital on Feb. 11, 1948, a three weeks' history of headache, *pain in the* left ear side of the face, neck stiffness, and increasing forming sentences. These symptoms had appeared wi 24 hours of her having a tooth filled. On examination, could say only "yes" and "no" and understood comma with difficulty. There was early bilateral papillœdema an right upper-motor-neurone facial weakness. The ears normal. During the next week the papillœdema seemed increase though *the other signs remained* stationary; diagnosis of temporal lobe abscess was made and on F the brain was needled under local anæsthetic. Only 2 pus could be aspirated (culture: *Staph. aureus*). P (25,000 units) was injected into the abscess cavity. No was felt with the needle.

The patient's speech and other signs rapidly improved she was discharged from hospital on April 1, 1948, *completely recovered. She* went back to her training stage career in the summer of 1948, and at first had diffic in concentrating and learning her lines. Last May she that she had completed her course and had also taken training in acrobatics. An electroencephalogram taken May showed random theta activity in the left temporal but no phase reversal and no spikes.

These last two cases were both diagnosed in the stages and one aspiration and penicillin-replac was all that was necessary.

Case 7.—*Boy aged 7. Fallot's tetralogy. January, 194 short-circuit operation. May, 1948: right frontal lobe absce treated by aspiration. Recovery.*

A short-circuit operation for Fallot's tetralogy was performed in January, 1948, by Mr. R. C Brock. The patient was admitted to hospital again on April 21, 1948, having had two attacks of twitching of the left side of the face which had been preceded by right-sided headache. His lungs were clear *and the only* abnormal sign in the central nervous system a left facial weakness. On April 28 he had a fit which left paralysed on the left side for three hours; but later there a partial recovery of function. He gradually became drowsy and his left-sided weakness developed into a flaccid hemiplegia; he also developed papillœdema and rigidity. A frontal-lobe brain abscess was diagnosed.



—Blood-pressure steady and block allowed to wear off but stituted as blood-pressure rose again. Compare low pulse-ssure with that in fig. 4.

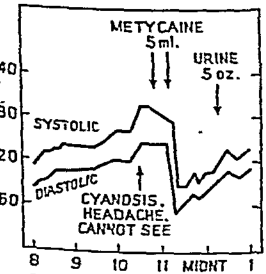
TECHNIQUE AND MANAGEMENT

careful nursing and sedation do not control the l-pressure, other methods must be adopted. Of a lumbar peridural block should be the first choice, spinal and caudal block as second and third choices. eridural block spares the motor nerves, leaving icter control intact and thereby reducing the ing problem. The disadvantage of the caudal block ie difficulty in attaining a satisfactory height of gesia, with consequent unsatisfactory control of the l-pressure.

lumbar peridural block is done with a 16-gauge Tuohy e with the usual aseptic precautions. Through this is ted a length of polythene tubing (no. 1 gauge, external eter 1 mm.) so that the tip comes to lie in the region of 10th thoracic segment. The needle is then withdrawn, ng the tubing in place. The point of entry of the tubing xt sealed with soft-paraffin gauze or sulphonamide oint-, these dressings being firmly anchored with adhesive ping. The free end of the tubing is brought round to the ior abdominal wall and is secured there with a piece of ping throughout its length. Injections may be made the tubing as required. The tubing should be long gh to allow easy access for injection whatever the position e patient.

ie point in the maintenance of asepsis deserves special tion. The free end of the polythene tubing must be ped in sterile gauze after each injection, with the needle u. To prevent leakage and infection it is necessary to seal his end between each injection. If a syringe remains hed and is strapped to the body it will gradually work , and the needle tip will saw through the wall of the ng. This difficulty was overcome by using a needle adapter, se lumen had been sealed with solder, in place of the ige.

r a *spinal block* an identical technique is used, the only rence being in the site of the needle tip. If anxiety is felt about asepsis, a sample of cerebrospinal fluid may be withdrawn from the polythene tubing for examination, and a course of intrathecal crystalline penicillin 10,000 units six-hourly started.



3—Effect of reduction of blood-ressure on excretion of urine.

Our experience in this case supports the view of Hughes et al. (1948), that as a general rule metycaine $1^1/_2\%$ is preferable to longer-acting drugs. Metycaine is effective only for about 45 minutes, and if the level anæsthesia is too high the embarrassment caused will correspondingly brief. Further, since diuresis may be moted by a swinging blood-pressure (Hingson 1949), nay be undesirable to stabilise the blood-pressure at one level for the length of time that a drug such as upercaine' continues to act.

The level of skin anæsthesia furnishes a rough guide the dosage of local anæsthetic required but its assessment requires the coöperation of the patient. The blood-pressure is a more accurate guide and indicates the efficacy of the treatment. The dose of local anæsthetic must be adjusted to obtain the blood-pressure considered most suitable. A constant blood-pressure is least harmful to a damaged heart, so, though a swinging blood-pressure is more effective in promoting diuresis, the blood-pressure must be controlled within limits which the patient's heart can tolerate; for this the pulse-rate and the pulse-pressure are the most satisfactory guides. These criteria are not absolute, however, and there is a constant risk of precipitating acute heart-failure. Fig. 1 shows a swinging blood-pressure culminating in acute heart-failure characterised by cyanosis, dyspnœa, tachycardia, and pulmonary œdema. Fig. 2, on the other hand, covers an earlier period during the same day when the blood-pressure was stable. During the 12 hours covered by fig. 1 22 oz. of urine was excreted, compared with 16 oz. during the 12 hours covered by fig. 2; this may illustrate the contention that urinary output is increased by a swinging blood-pressure.

The immediate effect of a reduction in blood-pressure on the output of urine is seen in fig. 3. For $4^1/_2$ hours no urine had been excreted. When the blood-pressure fell 5 oz. of urine was excreted. This diuresis was a sequel to a precipitate fall in blood-pressure, which had to be combated by supportive measures. The necessity of reducing the blood-pressure to excité the excretion of urine may also become obvious by allowing the block to wear off. When the blood-pressure rose very high, the urinary output appeared to fall progressively.

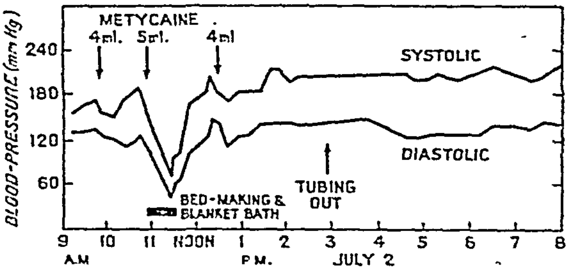


Fig. 4—Blood-pressure remains steady as effect of spinal block wears off. Note hypotensive episode precipitated by bed-making and blanket bath.

In the present case recovery permitted a higher blood-pressure to be maintained without danger. As time went on, it became necessary only to limit peaks in blood-pressure with smaller and less frequent injections. Fig. 4 shows that, when the block was allowed to wear off, the blood-pressure remained steady at about 200/140 mm. Hg and the patient's general condition was satisfactory. There were no visual disturbances, headache, or signs of heart-failure, and diuresis was maintained.

NURSING

The maintenance of a continuous peridural or spinal block should not interfere with normal nursing, but some special points need emphasis.

Blood-pressure and pulse-rate must be recorded frequently, and the patient's general state watched carefully for respiratory embarrassment or the increasing restlessness which often presages a rise in blood-pressure. Patients under a spinal block are intolerant of movement. Fig 4 shows a hypotensive episode precipitated by bed-making and washing. Supportive measures must be to hand to combat crises resulting from movement or from too high a level of anæsthesia. Briefly these measures are tipping the bed, oxygen, and 'Methedrine.' Owing to the pooling of blood in dilated blood-vessels, the raising of both the patient's legs to a right angle with his body is equivalent to an autotransfusion of nearly a litre, and is a valuable manœuvre in attempting to raise a fallen blood-pressure.

Loss of sphincter control under a spinal block necessitates the use of an indwelling catheter. A rectal tube may be interest. Unforeseen problems arise when any new technique is attempted, and the opportunities for applying these methods so seldom arise that, though it is rash to draw conclusions from a single experience, we are prompted to describe this case in the hope that others who wish to use the method may benefit from a report of the difficulties we encountered.

CASE-RECORD

A primipara, aged 21, was admitted to the Radcliffe Infirmary on June 25, 1949, with severe oliguria following delivery of a stillborn child at 35 weeks' gestation.

Her past history was uneventful. Antenatal supervision was carried out at another hospital. The blood-pressure was first recorded at 19 weeks' gestation, when it was 140/80 mm. Hg, and the urine was normal. The blood-pressure remained at 140/80, and, though at 26 weeks the blood-urea was 42 mg. per 100 ml., the pregnancy was regarded as normal until 32 weeks, when the blood-pressure rose to 140/90 without albuminuria. At 34 weeks the blood-pressure was 150/90 and there was albuminuria, so the patient was advised diet and rest. Within three days diarrhœa and vomiting developed, and she was admitted to hospital at 4 P.M. on June 23 in spontaneous labour at 35 weeks. She complained of headache and "seeing stars," her blood-pressure was 190/150, and catheterisation did not produce any urine. Intravenous therapy was started. On June 24 at 4 A.M. the patient was delivered of a stillborn child weighing 3 lb. 10 oz. Sixteen hours after admission $^1/_4$ oz. of urine was obtained by catheter; this specimen contained blood, white cells, and albumin. In the 2 days following admission the patient was given 2 litres of glucose solution and 1$^1/_2$ litres of sodium sulphate solution intravenously, and less than 2 oz. of urine was passed. Intravenous therapy was then abandoned for fear of overloading the circulation, and the patient was transferred to the Radcliffe Infirmary on June 25. There was no history of convulsions.

On admission at 8.30 P.M. the patient was very pale and lethargic, with gross generalised œdema and a bloated and waxy face. Her temperature was 98·8°F, pulse-rate 92 per min., and blood-pressure 170/100 mm. Hg. There was no papillœdema or retinal change. No abnormality was detected clinically in the chest or heart. The fundus uteri was palpable 4 in. above the symphysis; there was bruising of the external genitalia; the lochia were normal; and the breasts showed minimal secretion. Less than 2 oz. of urine had been excreted in the 52 hours since labour started.

Treatment.—The patient was treated on orthodox lines in a darkened room, with a special nurse in attendance. Sedation was begun with diamorphine hydrochloride gr. $^1/_{12}$ and phenobarbitone sodium gr. 3, and maintained with paraldehyde and 'Sodium amytal.' Penicillin 500,000 units six-hourly was given to guard against intercurrent infection. It was considered dangerous to give 'Sulphamezathine' in the presence of such severe oliguria, though the risk of urinary-tract infection was appreciated. Since the Hb was only 61% (Haldane), the packed cells of two pints of blood of the patient's group (group O, Rh-negative) were transfused on June 25, followed next day by the packed cells of a further two pints of blood, since the Hb had risen only to 72%. By 10 P.M., 2 hours after admission, the patient was quiet; 'Polythene' tubing was passed through the nose stomach and an intragastric drip was started, carbohydrate 400 g. and fat 100 g. emulsified in a water. This was continued for eight days, a litre of emulsion being given daily and supplemented by combat excessive loss of fluid by diarrhœa. The pol tubing provoked minimal retching and little vomiting.

Progress.—At 6 P.M. on June 26, 22 hours after the patient had transient symptoms of cerebral irritation. blood-pressure was 210/140 mm. Hg, and sedation deepened. In the 24 hours after admission 4$^1/_2$ oz of was excreted; this contained 400 mg. of protein per an occasional pus cell, and some red cells. The blood 90 mg. per 100 ml., and the plasma-protein 4·95 g. per On June 27 the blood-pressure remained the same, patient complained of headache and her pulse-rate was Since deep sedation did not lower the blood-pressure, other means was sought.

At 8 P.M. a caudal block was established to the level fifth thoracic segment in the hope of controlling pressure and stimulating diuresis. From this time one of us was in constant attendance. The block was for 22 hours with 'Metycaine' 1$^1/_2$%, with little effect on pressure or urinary output, but with less mental On June 28, with the blood-pressure still 210/140, the became increasingly irrational; she finally lost and there were muscular twitchings of her face limbs.

At this time we were fortunate in having the Dr. Hingson, who suggested a continuous spinal block.

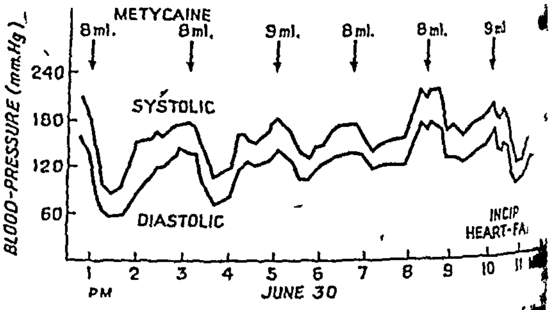

Fig. 1—Swinging blood-pressure culminating in acute heart-fa

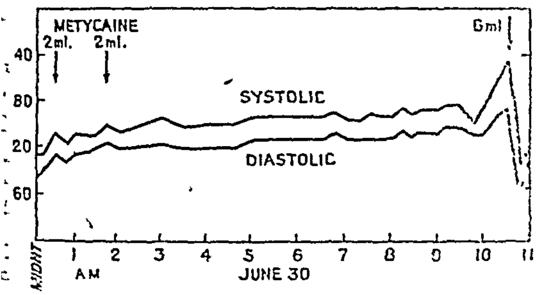
soon as the block was established and the blood pr lowered, there was a spectacular change in the pat general condition: consciousness returned and the twitc ceased, though there was no striking increase in ur output. The spinal block was maintained for 4$^1/_2$ da control the blood-pressure. As the block wore off, the bl pressure rose and cerebral disturbance returned. On t occasions incipient heart-failure developed, manifested falling pulse pressure and pulmonary œdema. Each time spinal block was intensified, the blood-pressure fell, and crisis was averted. On the fifth day of block (the seventh after admission) the pulse pressure had increased and blood-pressure had become stable at 200/140 mm. Hg; the block was allowed to wear off. This blood pr though higher than the patient's normal level, did not le heart-failure or cerebral disturbance, and as she seemed fortable the spinal tubing was removed. After the attack of acute heart-failure digitalis and aminophylline given.

The patient's progress gave reasonable prospect of recovery. On clinical grounds the renal lesion was re as probably a lower-nephron nephrosis. Kidney function steadily improving, shown by a urine output rising to than 2 litres a day and a urea excretion rising from le 1 g. per 24 hours on June 26 to 8·5 g. on July 1 and 21. on July 4 (normal up to 32 g. per 24 hours). The ing table summarises the relevant laboratory inv

On July 6 the patient felt very well; she was reading, and demanding a full diet, but becoming of restrictions on her activity. In an unguarded when the nurse left the room to fetch a bedpan, she got of bed; the effort being too much for her, she collapsed died almost immediately. The necropsy findings are and discussed below.



—Blood-pressure steady and block allowed to wear off but stituted as blood-pressure rose again. Compare low pulse-sure with that in fig. 4.

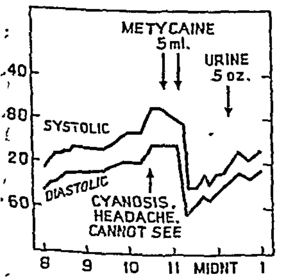
TECHNIQUE AND MANAGEMENT

careful nursing and sedation do not control the l-pressure, other methods must be adopted. Of a lumbar peridural block should be the first choice, spinal and caudal block as second and third choices. eridural block spares the motor nerves, leaving icter control intact and thereby reducing the ng problem. The disadvantage of the caudal block e difficulty in attaining a satisfactory height of gesia, with consequent unsatisfactory control of the l-pressure.

lumbar peridural block is done with a 16-gauge Tuohy e with the usual aseptic precautions. Through this is ed a length of polythene tubing (no. 1 gauge, external eter 1 mm.) so that the tip comes to lie in the region of 0th thoracic segment. The needle is then withdrawn, ng the tubing in place. The point of entry of the tubing xt sealed with soft-paraffin gauze or sulphonamide oint-, these dressings being firmly anchored with adhesive ping. The free end of the tubing is brought round to the ior abdominal wall and is secured there with a piece of ping throughout its length. Injections may be made the tubing as required. The tubing should be long gh to allow easy access for injection whatever the position e patient.

ie point in the maintenance of asepsis deserves special ion. The free end of the polythene tubing must be ped in sterile gauze after each injection, with the needle u. To prevent leakage and infection it is necessary to seal his end between each injection. If a syringe remains hed and is strapped to the body it will gradually work , and the needle tip will saw through the wall of the ng. This difficulty was overcome by using a needle adapter, se lumen had been sealed with solder, in place of the ige.

r a *spinal block* an identical technique is used, the only rence being in the site of the needle tip. If anxiety is felt about asepsis, a sample of cerebrospinal fluid may be withdrawn from the polythene tubing for examination, and a course of intrathecal crystalline penicillin 10,000 units six-hourly started.



3—Effect of reduction of blood-ressure on excretion of urine.

Our experience in this case supports the view of Hughes et al. (1948), that as a general rule metycaine $1^1/_2\%$ is preferable to longer-acting drugs. Metycaine is effective only for about 45 minutes, and if the level anæsthesia is too high the embarrassment caused will correspondingly brief. Further, since diuresis may be omoted by a swinging blood-pressure (Hingson 1949), may be undesirable to stabilise the blood-pressure at y one level for the length of time that a drug such as upercaine' continues to act.

The level of skin anæsthesia furnishes a rough guide the dosage of local anæsthetic required but its assessment requires the coöperation of the patient. The blood-pressure is a more accurate guide and indicates the efficacy of the treatment. The dose of local anæsthetic must be adjusted to obtain the blood-pressure considered most suitable. A constant blood-pressure is least harmful to a damaged heart, so, though a swinging blood-pressure is more effective in promoting diuresis, the blood-pressure must be controlled within limits which the patient's heart can tolerate; for this the pulse-rate and the pulse-pressure are the most satisfactory guides. These criteria are not absolute, however, and there is a constant risk of precipitating acute heart-failure. Fig. 1 shows a swinging blood-pressure culminating in acute heart-failure characterised by cyanosis, dyspnœa, tachycardia, and pulmonary œdema. Fig. 2, on the other hand, covers an earlier period during the same day when the blood-pressure was stable. During the 12 hours covered by fig. 1 22 oz. of urine was excreted, compared with 16 oz. during the 12 hours covered by fig. 2; this may illustrate the contention that urinary output is increased by a swinging blood-pressure.

The immediate effect of a reduction in blood-pressure on the output of urine is seen in fig. 3. For $4^1/_2$ hours no urine had been excreted. When the blood-pressure fell 5 oz. of urine was excreted. This diuresis was a sequel to a precipitate fall in blood-pressure, which had to be combated by supportive measures. The necessity of reducing the blood-pressure to excite the excretion of urine may also become obvious by allowing the block to wear off. When the blood-pressure rose very high, the urinary output appeared to fall progressively.

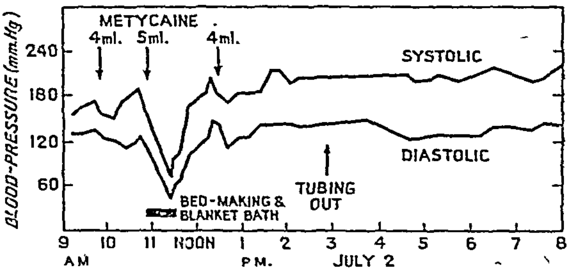


Fig. 4—Blood-pressure remains steady as effect of spinal block wears off. Note hypotensive episode precipitated by bed-making and blanket bath.

In the present case recovery permitted a higher blood-pressure to be maintained without danger. As time went on, it became necessary only to limit peaks in blood-pressure with smaller and less frequent injections. Fig. 4 shows that, when the block was allowed to wear off, the blood-pressure remained steady at about 200/140 mm. Hg and the patient's general condition was satisfactory. There were no visual disturbances, headache, or signs of heart-failure, and diuresis was maintained.

NURSING

The maintenance of a continuous peridural or spinal block should not interfere with normal nursing, but some special points need emphasis.

Blood-pressure and pulse-rate must be recorded frequently, and the patient's general state watched carefully for respiratory embarrassment or the increasing restlessness which often presages a rise in blood-pressure. Patients under a spinal block are intolerant of movement. Fig 4 shows a hypotensive episode precipitated by bed-making and washing. Supportive measures must be to hand to combat crises resulting from movement or from too high a level of anæsthesia. Briefly these measures are tipping the bed, oxygen, and 'Methedrine.' Owing to the pooling of blood in dilated blood-vessels, the raising of both the patient's legs to a right angle with his body is equivalent to an autotransfusion of nearly a litre, and is a valuable manœuvre in attempting to raise a fallen blood-pressure.

Loss of sphincter control under a spinal block necessitates the use of an indwelling catheter. A rectal tube may be convenient if incontinence of fæces is aggravated by a high-fat diet.

Paresis of the legs following a spinal block demands careful attention to prevent foot-drop.

Records.—It was found useful to record all observations, especially blood-pressure, pulse-rate, and fluid balance, on a continuous chart rather than in the form of notes.

Constant Attendance.—A special nurse must be in constant attendance so that the patient is never left unguarded.

DISCUSSION

In adopting this treatment for the present case, it was hoped that there might be a twofold effect—the promotion of diuresis and the control of blood-pressure. Our limited experience of such cases led us first to use a caudal block, which produced neither of these effects; and with the patient's condition deteriorating rapidly, Dr. Hingson advised a continuous spinal block. This controlled the blood-pressure, with a spectacular improvement in the patient's general condition. There was, however, no immediate diuresis. The reason for this may have been that the anuria resulted primarily from angiospasm, causing ischæmia, which led to structural damage of the kidneys owing to the length of time that the condition remain untreated. Even though the reflex spasm was broken when the spinal block was first instituted, a certain time presumably had to elapse before any function could return to the damaged kidneys. Columnar epithelia are known to be able to regenerate, so repair of tubular damage is possible, whereas capillary damage in the complex glomerulus is less rapidly repaired. Even if the spinal block played no part in restoring kidney function, death was undoubtedly averted by the prevention of hypertensive crises. Nevertheless, in numerous reported cases (Hingson et al. 1947) diuresis has immediately followed the institution of a block, and it seems that the briefer the anuria the more striking the response.

In the present case an effective block was only started after four days' almost complete anuria. In retrospect, it seems that a continuous lumbar peridural block should have been instituted in the first place.

Fluid balance (fig. 5) was maintained on the lines advocated by Bull et al. (1949). The rationale is restriction of fluid intake to balance current fluid loss, together with a high-carbohydrate and high-fat diet, which reduces protein katabolism to a minimum. This diet is so unpalatable that it is best given by a continuous gastric drip through the nose. Owing to the massive loss of fluid per rectum, doubtless caused by the combination of a high-fat diet and spinal block, it was thought necessary to supplement the fluid intake with drinks.

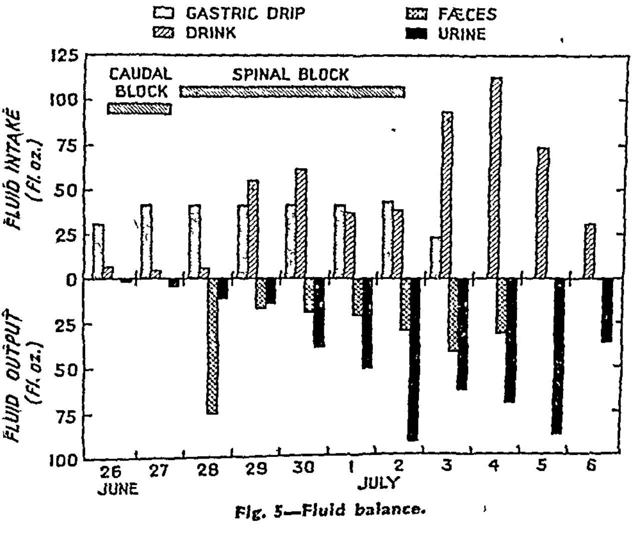

Fig. 5—Fluid balance.

When a rise in blood-pressure was a restlessness, confusion, and headache, this as a warning of imminent heart-failure. R alone could be ascribed to return of sensation as effect of the local anæsthetic wore off. Sedatives prescribed as required.

These cases call for close coöperation between rician, physician, and anæsthetist; but once the phase is over the management becomes a problem.

The unfortunate sequel to the present case is no tion on the treatment described here. Though ultimate prognosis may not have been good, adequate rest and medical treatment this patient reasonably have been expected to survive the As it was, after days and nights of constant att the patient was left for one unguarded moment she seemed to have survived the immediate dangers. that moment she died.

NECROPSY FINDINGS

(R. A. SLADDEN)

Only the more significant findings are mentioned.

Naked-eye Appearances

The heart weighed 450 g., its cavities were not dilated, its muscle was pale and flabby. The lungs showed subp petechial hæmorrhages, and basal congestion of the right The liver weighed 1000 g. and subcapsular and petechial hæmorrhages were present. The right kidney 160 g. and the left 270 g. Both were very pale, with streaky red areas of vascular congestion on the surfaces. The capsules stripped readily. The cut surface rather granular. The cortex was very pale, and a few could be seen with the naked eye in the deeper layers medullary vessels were prominent, but the substance of pyramids was pale and blurred. In the uterus some adhered to the placental site, and there were stromal hæmorrhages in the myometrium. The ovaries showed extensive stromal hæmorrhages. The showed bilateral medullary and cortical hæmorrhages; was distributed in irregular streaks. The other organs appea normal. There was no evidence of infection at the site of caudal and spinal blocks.

Microscopical Appearances

Liver: the hepatic cells were, on the whole, well preserv and showed no increase in fat. There was some dilatation sinusoids and proliferation of Kupffer cells. Focal areas periportal zonal hepatic necrosis were present, with infla matory and hæmorrhagic infiltration. A few afferent hep capillaries showed fibrinoid necrosis, and small fibrin thro were present both in these capillaries and in branches of portal vein. There was slight displacement, but no destructio of the reticulin network.

Kidneys: thick frozen sections were prepared by Fie worth's method to show the distribution of blood. For th most part the cortical vessels contained no erythrocytes though in small focal areas at the periphery the peritubula capillaries were well filled with blood and the glomeruli wer infarcted. In the remainder of the cortex the glomeruli bloodless, except for a few infarcted juxtamedullary glomerul The interlobular vessels were free from blood; the arcuat vessels contained blood and occasional small thrombi; and the vasa recta were engorged and prominent and showed some extravasation of blood. Ordinary sections confirmed this picture of the distribution of blood. The glomeruli showed proliferation of the tufts by endothelial hyperplasia and thickening of the basement membranes. The interlobular vessels were empty and otherwise normal, but subendothelial lymphoid aggregates were seen in some arcuate vessels, which also contained small fibrin thrombi. Vascular changes were most striking in the plexus underlying the pelvic mucosa, where many capillaries showed fibrinoid necrosis. The tubules showed widespread degeneration, but there was also considerable epithelial regeneration. The tubules were widely separated by interstitial œdema, and in places small granulomata had taken the place of destroyed tubular tissue. Hyaline casts, but no hæmoglobin casts, were present in some collecting tubules.

Suprarenals: fibrinoid necrosis was present in the cortical capillaries, together with considerable cortical necro ng chiefly the zona fasciculata. There was wide-spread rhage in both medulla and cortex, and recent thrombi ound in the larger veins of the medulla. The surviving il cells contained abundant lipoid.

itary: pregnancy cells were present, but there was no ice of necrosis.

THE GENERAL HOSPITAL, BIRMINGHAM

SES of severe hæmolytic anæmia associated with gkin's disease are sufficiently uncommon to warrant rding, though the incidence is probably greater the number of reported cases suggests. Davidson 2) described 3 cases, 2 of which were first diagnosed ernicious anæmia because of the macrocytic blood re and treated as such without effect; both of the ents died, and lymphadenomatosis was found at opsy; the third case was diagnosed during life. son (1939) mentioned 3 cases of macrocytic anæmia Hodgkin's disease, and Davis (1944) described hers. In all, 17 cases have been recorded.

xamples of hæmolytic anæmia with reticuloses other Hodgkin's disease have been published. Scott and b-Smith (1939) described 4 cases of hæmolytic anæmia with histiocytic medullary reticulosis, and Gittins (1933) reported a case of reticulo-endotheliosis with hæmolytic anæmia.

CASE-RECORD

An engineer, aged 56, was in good health until January, 1948, when he noted increasing lassitude and small swellings under his chin. His doctor, who saw him on Jan. 17, found enlarged submental and submaxillary lymph-glands, and suspected Hodgkin's disease. Before admission to hospital his hæmoglobin (Hb) was 84% (Haldane). He was admitted ten days later (Jan. 27) as an emergency.

On admission he was well nourished, stuporose, extremely pale, and slightly icteric. Respirations 25 and pulse-rate 120 per min., temperature 99°F, blood-pressure 100/60 mm. Hg. There were enlarged "rubbery" glands in the neck and right axilla. The spleen and liver were not palpable. The urine contained a trace of albumin with an excess of urobilinogen, but no bile pigment.

Blood: red cells 1,250,000 per c.mm., Hb 23% (3·2 g. per 100 ml.), colour-index 0·92, white cells 22,900 per c.mm. (polymorphs 87%, eosinophils 0·5%, basophils 0·5%, lymphocytes 2·5%, monocytes 5%, metamyelocytes 2%, Türk cells 2·5%). The red cells showed well-marked anisopoikilocytosis and polychromasia; 4 normoblasts per 100 leucocytes were found. Reticulocytes 11%. Blood-serum gave a positive direct van den Bergh reaction; serum-bilirubin 7·25 mg.; and blood-urea 65 mg. per 100 ml. Blood-grouping was difficult owing to spontaneous agglutination. The report (abridged) by Dr. W. Weiner, of the Regional Blood Transfusion Service, was: "Spontaneous agglutination occurred. The cells were thoroughly washed and resuspended. The cells were found to be group O and rhesus-positive. The pseudo-agglutination occurred at room, refrigeration, and incubation temperatures. The agglutinates could only be broken up by the addition of saline. A direct Coombs test was weakly positive." There was nothing in the history to indicate any exogenous cause of the hæmolytic process.

Other investigations: Donath-Landsteiner and acid hæmolysin tests were negative. Corpuscular fragility: in the patient, hæmolysis commencing in 0·48% saline and complete in 0·32%; in a control, hæmolysis commencing in 0·44% saline and complete in 0·32%. Radiography of the chest showed no evidence of mediastinal glandular enlargement.

Therapy included penicillin 50,000 units intramuscularly three-hourly and transfusions of fresh blood (packed cells) to the equivalent of $7\frac{1}{2}$ pints in five days. On Feb. 2 the man's Hb was 46%. Five days later it was 34%. Two further pints of fresh blood was given, and his Hb was then 40%. In about a week it had fallen to 25%.

Splenectomy.—The lymph-glands previously described were hardly palpable. Since the patient was destroying blood almost as rapidly as it was given, splenectomy was considered. After a series of blood-transfusions his Hb rose to 64%, and splenectomy was done. The spleen was about twice the normal size and easily removed. It weighed 300 g. (normal 155–200 g.). Microscopically it showed a fine diffuse fibrosis and reticulo-endothelial hyperplasia. The malpighian corpuscles were much diminished in size. Scattered throughout the section were many plasma cells, with occasional polymorphs, eosinophils, and Dorothy Reed cells. The striking feature was the erythrophagocytosis, many of the reticulo-endothelial cells being swollen with pigment giving a positive prussian-blue reaction. There were also some small infarcts. The picture was essentially that seen in an acute hæmolytic anæmia—i.e., dilatation of venous sinuses, with a few red cells and hæmosiderosis—but the pleomorphic cellular appearance with Dorothy Reed cells suggested Hodgkin's disease (fig. 1).

Progress.—The patient remained well, except that about a week later the neck glands, which previously seemed to recede, began to enlarge rapidly, becoming easily visible. The hæmolytic process seemed to have abated somewhat. Fourteen days after operation his Hb was 48%, red cells 2,450,000 per c.mm., colour-index 0·98, and white cells 16,400 per c.mm. (polymorphs 85%, eosinophils 1·5%, basophils 0, lymphocytes 7·5%, monocytes 5%, metamyelocytes 1%).

Lymph-node biopsy on March 12 showed a complete disorientation of lymph-nodal architecture, with diffuse proliferative changes of the medullary elements, diffuse fibrosis, convenient if incontinence of fæces is aggravated by a high-fat diet.

Paresis of the legs following a spinal block demands careful attention to prevent foot-drop.

Records.—It was found useful to record all observations, especially blood-pressure, pulse-rate, and fluid balance, on a continuous chart rather than in the form of notes.

Constant Attendance.—A special nurse must be in constant attendance so that the patient is never left unguarded.

DISCUSSION

In adopting this treatment for the present case, it was hoped that there might be a twofold effect—the promotion of diuresis and the control of blood-pressure. Our limited experience of such cases led us first to use a caudal block, which produced neither of these effects; and with the patient's condition deteriorating rapidly, Dr. Hingson advised a continuous spinal block. This controlled the blood-pressure, with a spectacular improvement in the patient's general condition. There was, however, no immediate diuresis. The reason for this may have been that the anuria resulted primarily from angiospasm, causing ischæmia, which led to structural damage of the kidneys owing to the length of time that the condition remain untreated. Even though the reflex spasm was broken when the spinal block was first instituted, a certain time presumably had to elapse before any function could return to the damaged kidneys. Columnar epithelia are known to be able to regenerate, so repair of tubular damage is possible, whereas capillary damage in the complex glomerulus is less rapidly repaired. Even if the spinal block played no part in restoring kidney function, death was undoubtedly averted by the prevention of hypertensive crises. Nevertheless, in numerous reported cases (Hingson et al. 1947) diuresis has immediately followed the institution of a block, and it seems that the briefer the anuria the more striking the response.

In the present case an effective block was only started *after four days' almost complete anuria. In retrospect, it seems that a continuous lumbar peridural block should have been instituted in the first place.*

Fluid balance (fig. 5) was maintained on the lines advocated by Bull et al. (1949). The rationale is restriction of fluid intake to balance current fluid loss, together with a high-carbohydrate and high-fat diet, which reduces protein katabolism to a minimum. This diet is so unpalatable that it is best given by a continuous gastric drip through the nose. Owing to the massive loss of fluid per rectum, doubtless caused by the combination of a high-fat diet and spinal block, it was thought necessary to supplement the fluid intake with drinks.

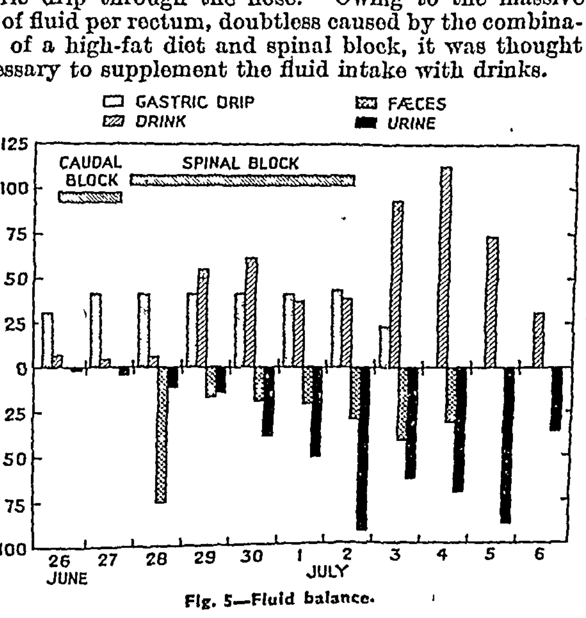

Fig. 5—Fluid balance.

When a rise in blood-pressure was a restlessness, confusion, and headache, this was as a warning of imminent heart-failure. F alone could be ascribed to return of sensation effect of the local anæsthetic wore off. Sedatives prescribed as required.

These cases call for close coöperation between rician, physician, and anæsthetist; but once the phase is over the management becomes a problem.

The unfortunate sequel to the present case is no tion on the treatment described here. Though ultimate prognosis may not have been good, adequate rest and medical treatment this patient reasonably have been expected to survive the As it was, after days and nights of constant at the patient was left for one unguarded moment she seemed to have survived the immediate dangers. that moment she died.

NECROPSY FINDINGS

(R. A. SLADDEN)

Only the more significant findings are mentioned.

Naked-eye Appearances

The heart weighed 450 g., its cavities were not dilated, its muscle was pale and flabby. The lungs showed petechial hæmorrhages, and basal congestion of the right The liver weighed 1900 g. and subcapsular and petechial hæmorrhages were present. The right kidney w 160 g. and the left 270 g. Both were very pale, with streaky red areas of vascular congestion on the surfaces. The capsules stripped readily. The cut surface rather granular. The cortex was very pale, and a few could be seen with the naked eye in the deeper layers medullary vessels were prominent, but the substance of pyramids was pale and blurred. In the uterus some adhered to the placental site, and there were stromal hæmorrhages in the myometrium. The ovaries showed extensive stromal hæmorrhages. The supraren showed bilateral medullary and cortical hæmorrhages; lip was distributed in irregular streaks. The other organs normal. There was no evidence of infection at the site of caudal and spinal blocks.

Microscopical Appearances

Liver: the hepatic cells were, on the whole, well preserv and showed no increase in fat. There was some dilatation sinusoids and proliferation of Kupffer cells. Focal areas periportal zonal hepatic necrosis were present, with infla matory and hæmorrhagic infiltration. A few afferent hep capillaries showed fibrinoid necrosis, and small fibrin thr were present both in these capillaries and in branches of portal vein. There was slight displacement, but no destruc of the reticulin network.

Kidneys: thick frozen sections were prepared by Pi worth's method to show the distribution of blood. For th most part the cortical vessels contained no erythrocytes though in small focal areas at the periphery the per capillaries were well filled with blood and the glomeruli infarcted. In the remainder of the cortex the glomeruli bloodless, except for a few infarcted juxtamedullary glomerul The interlobular vessels were free from blood; the arcua vessels contained blood and occasional small thrombi; an the vasa recta were engorged and prominent and showed so extravasation of blood. Ordinary sections confirmed th picture of the distribution of blood. The glomeruli showed proliferation of the tufts by endothelial hyperplasia and thickening of the basement membranes. The interlobular vessels were empty and otherwise normal, but subendothelial lymphoid aggregates were seen in some arcuate vessels, which also contained small fibrin thrombi. Vascular changes were most striking in the plexus underlying the pelvic mucosa, where many capillaries showed fibrinoid necrosis. The tubules showed widespread degeneration, but there was also considerable epithelial regeneration. The tubules were widely separated by interstitial œdema, and in places small granulomata had taken the place of destroyed tubular tissue. Hyaline casts, but no hæmoglobin casts, were present in some collecting tubules.

Suprarenals: fibrinoid necrosis was present in the cortical capillaries, together with considerable cortical necros ng chiefly the zona fasciculata. There was widespread rhage in both medulla and cortex, and recent thrombi ound in the larger veins of the medulla. The surviving d cells contained abundant lipoid.

itary: pregnancy cells were present, but there was no ce of necrosis.

THE GENERAL HOSPITAL, BIRMINGHAM

CASES of severe hæmolytic anæmia associated with odgkin's disease are sufficiently uncommon to warrant cording, though the incidence is probably greater an the number of reported cases suggests. Davidson 932) described 3 cases, 2 of which were first diagnosed pernicious anæmia because of the macrocytic blood cture and treated as such without effect; both of the tients died, and lymphadenomatosis was found at cropsy; the third case was diagnosed during life. atson (1939) mentioned 3 cases of macrocytic anæmia ith Hodgkin's disease, and Davis (1944) described others. In all, 17 cases have been recorded.

Examples of hæmolytic anæmia with reticuloses other an Hodgkin's disease have been published. Scott and obb-Smith (1939) described 4 cases of hæmolytic anæmia with histiocytic medullary reticulosis, and Gittins (1933) reported a case of reticulo-endotheliosis with hæmolytic anæmia.

CASE-RECORD

An engineer, aged 56, was in good health until January, 1948, when he noted increasing lassitude and small swellings under his chin. His doctor, who saw him on Jan. 17, found enlarged submental and submaxillary lymph-glands, and suspected Hodgkin's disease. Before admission to hospital his hæmoglobin (Hb) was 84% (Haldane). He was admitted ten days later (Jan. 27) as an emergency.

On admission he was well nourished, stuporose, extremely pale, and slightly icteric. Respirations 25 and pulse-rate 120 per min., temperature 99°F, blood-pressure 100/60 mm. Hg. There were enlarged "rubbery" glands in the neck and right axilla. The spleen and liver were not palpable. The urine contained a trace of albumin with an excess of urobilinogen, but no bile pigment.

Blood: red cells 1,250,000 per c.mm., Hb 23% (3·2 g. per 100 ml.), colour-index 0·92, white cells 22,900 per c.mm. (polymorphs 87%, eosinophils 0·5%, basophils 0·5%, lymphocytes 2·5%, monocytes 5%, metamyelocytes 2%, Türk cells 2·5%). The red cells showed well-marked anisopoikilocytosis and polychromasia; 4 normoblasts per 100 leucocytes were found. Reticulocytes 11%. Blood-serum gave a positive direct van den Bergh reaction; serum-bilirubin 7·25 mg.; and blood-urea 65 mg. per 100 ml. Blood-grouping was difficult owing to spontaneous agglutination. The report (abridged) by Dr. W. Weiner, of the Regional Blood Transfusion Service, was: "Spontaneous agglutination occurred. The cells were thoroughly washed and resuspended. The cells were found to be group O and rhesus-positive. The pseudo-agglutination occurred at room, refrigeration, and incubation temperatures. The agglutinates could only be broken up by the addition of saline. A direct Coombs test was weakly positive." There was nothing in the history to indicate any exogenous cause of the hæmolytic process.

Other investigations: Donath-Landsteiner and acid hæmolysin tests were negative. Corpuscular fragility: in the patient, hæmolysis commencing in 0·48% saline and complete in 0·32%; in a control, hæmolysis commencing in 0·44% saline and complete in 0·32%. Radiography of the chest showed no evidence of mediastinal glandular enlargement.

Therapy included penicillin 50,000 units intramuscularly three-hourly and transfusions of fresh blood (packed cells) to the equivalent of $7^1/_2$ pints in five days. On Feb. 2 the man's Hb was 46%. Five days later it was 34%. Two further pints of fresh blood was given, and his Hb was then 40%. In about a week it had fallen to 25%.

Splenectomy.—The lymph-glands previously described were hardly palpable. Since the patient was destroying blood almost as rapidly as it was given, splenectomy was considered. After a series of blood-transfusions his Hb rose to 64%, and splenectomy was done. The spleen was about twice the normal size and easily removed. It weighed 300 g. (normal 155–200 g.). Microscopically it showed a fine diffuse fibrosis and reticulo-endothelial hyperplasia. The malpighian corpuscles were much diminished in size. Scattered throughout the section were many plasma cells, with occasional polymorphs, eosinophils, and Dorothy Reed cells. The striking feature was the erythrophagocytosis, many of the reticulo-endothelial cells being swollen with pigment giving a positive prussian-blue reaction. There were also some small infarcts. The picture was essentially that seen in an acute hæmolytic anæmia—i.e., dilatation of venous sinuses, with a few red cells and hæmosiderosis—but the pleomorphic cellular appearance with Dorothy Reed cells suggested Hodgkin's disease (fig. 1).

Progress.—The patient remained well, except that about a week later the neck glands, which previously seemed to recede, began to enlarge rapidly, becoming easily visible. The hæmolytic process seemed to have abated somewhat. Fourteen days after operation his Hb was 48%, red cells 2,450,000 per c.mm., colour-index 0·93, and white cells 16,400 per c.mm. (polymorphs 85%, eosinophils 1·5%, basophils 0, lymphocytes 7·5%, monocytes 5%, metamyelocytes 1%).

Lymph-node biopsy on March 12 showed a complete disorientation of lymph-nodal architecture, with diffuse proliferative changes of the medullary elements, diffuse fibrosis,

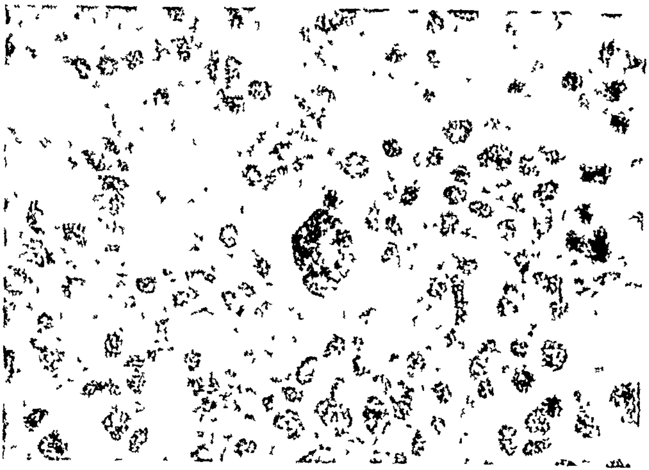

Fig. 1—Spleen showing fine fibrosis, polymorphic infiltration, and giant cell. (× 533.)

and a well-marked *plasma-cell reaction. Occasional* Dorothy Reed cells were present. The picture suggested Hodgkin's disease (fig. 2). On the strength of this report, deep X-ray therapy to the neck, inguinal regions, and axillæ was begun. From March 19 to April 16 a total dose of 10,800 r was given. The result was dramatic, and without further blood-transfusion the man's Hb rose from 54 to 84%. At this time the mean cell volume was 108 c.μ. and mean corpuscular Hb concentration 28%; reticulocytes were 4·2% and platelets 542,000 per c.mm. On April 17, about four months after his admission, the patient was discharged.

Readmission.—The patient continued fairly well as an outpatient until July, when he was readmitted with a recurrence of the hæmolytic process. He now showed signs of congestive cardiac failure, and a large gland was palpable in the left submaxillary region.

Blood: red cells 1,730,000 per c.mm., Hb 34%, colour-index 1, white cells 7950 per c.mm. (unsegmented polymorphs 4%, polymorphs 27·5%, eosinophils 7%, basophils 1%, lymphocytes 40·5%, monocytoid cells 18·5%; 28 normoblasts were seen per 100 white cells. The red cells showed well-marked anisopoikilocytosis and polychromasia. Serum: bilirubin 6 mg. per 100 ml.; van den Bergh, direct negative, indirect positive; spectroscopy showed no methæmoglobin but methæmalbumin was identified.

Next day the patient's Hb was 20%, with red cells 840,000 and platelets 320,000 per c.mm. He died that day; *necropsy* was refused.

DISCUSSION

Davis (1944) states: "In hæmolytic anæmias secondary to the reticuloses, it is not improbable that the abnormal red cell destruction may result directly from phagocytosis by proliferating histiocytes." The obvious criticism of this is that one would expect anæmia to be common in the reticuloses, whereas reverse is true. Possibly the association here is of chance; yet from the history in the present seemed to be a definite correlation between the endothelial hyperplasia and the hæmolytic Certainly, after *splenectomy the hæmolytic* abated, and when this was followed by deep therapy the hæmoglobin level rose spontaneously. *recurrence of the hæmolytic* process was associated further enlargement of glands.

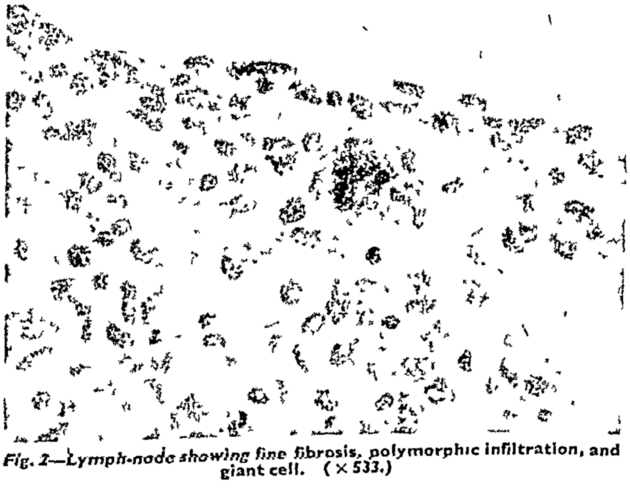

Fig. 2—Lymph-node showing fine fibrosis, polymorphic infiltration, and giant cell. (× 533.)

SUMMARY

A case of severe *hæmolytic anæmia* with a re is described.

Splenectomy depressed the hæmolytic temporarily.

Deep X-ray therapy caused a remission, for three months.

Thanks are due to Dr. J. M. Malins, under whose care patient was admitted, for permission to publish, to R. Gaddie for his biochemical reports; to Dr. J. L for the histological report on the lymph gland, to W. Weiner, of the Birmingham *Regional Blood* T Service, for his report on the serology; and to Miss P Weight for secretarial assistance.

HEAT CRAMPS

W. S. S. LADELL
M.B. Camb.

From the Colonial Medical Research Committee Laborator Hot Climate Physiology, Oshodi, Nigeria

Ladell, Waterlow, and Hudson (1944), in their inve gation in Iraq, found that 70% of their type I he exhaustion cases complained of cramp. In later te by the Medical Research Council Heat Research Te (Ladell 1947) some subjects had cramp fairly frequent

The factors concerned in cramp were first by Moss (1922) for coalminers. His insistence that was primarily caused by copious drinking of water aft long-continued sweating led Haldane (1923) to that it was a manifestation of water intoxication. from observations at the Boulder Dam and Talbott (1935) concluded that the chief factors we the losses of base, chloride, and water that occur dur heavy sweating; for cramp may occur when water not drunk to excess or even when it is not drunk at all.

It is usually accepted that in heat cramp there always a fall in the chloride content of the blood an plasma. Talbott reported that cramp supervened whe over the plasma chloride fell below 100 m.eq. per lit but other workers gave a lower figure; for examp McCance (1936) found plasma chlorides of less th 90 m.eq. in his *salt-deficient* subjects who develope cramp, and the average plasma chloride concentratio in type I heat-exhaustion cases was 79 m.eq. The observations reported below suggest that water intoxication and chloride loss are equally important.

EXPERIMENTAL OBSERVATIONS

In the Heat Research Team's experiments one subject (W. S. S. L.) was found to be peculiarly susceptible to cramp; he was physically fit and was in every wa normal. Electro-encephalography, both before and after exposure to the heat and after superhydration, showed no unusual cortical activity. This subject was exercised many *times in the heat* solely with the object of producing

›s so that they might be studied more closely; in sts accurate salt and water balances were kept ll 1948), and these are shown in table I.

26 occasions a negative salt balance was incurred; lean negative balance was 21·26 g. ranging from 11 g. On 20 of these occasions the subject complained ımp, which was confirmed objectively by palpation e cramped muscle. On 2 occasions, however, he was nly free from cramp but felt in excellent condition e when he had a negative salt balance of 18 g. and ıot in water debt, and once when he had a negative balance of 29 g. and a negative water balance of ml. On the 4 other occasions where there was a ive salt balance he did not complain of cramp, but eel somewhat exhausted.

the remaining 5 of the 31 tests in which balances were the subject took salt and his negative salt balance very small or negligible; in none of these did he ramp or feel at all crampy. On 6 other occasions ı he exercised in the heat but balances were not he failed to get cramp twice only, once when he taking salt and once when he sweated only about re.

ıese results show that, in this subject, cramps did levelop unless he became salt-deficient to the extent least 10 g., but that he did, at times, become severely deficient without developing cramp. His cramp ed in all important points with those described by ott, McCance, and others. The cramp was always eded by fasciculation of the muscle affected; this culation was similar to, but more pronounced than, twitching seen in a muscle ordinarily fatigued. The ap itself consisted of a localised contraction affecting w muscle bundles only; the cramped bundles could accurately located by the patient, and the hard tracted mass could be palpated by the observer. The le muscle mass was never affected all at one time, as one lot of bundles relaxed, another adjacent lot tracted, giving the impression of the cramp wandering r the muscle.

uring the periods when attacks of cramp could be voked, muscle action currents were recorded by Dr. G. Dawson. It was found that during cramp definite changes occurred which, though not peculiar to this condition, sufficed in the context of these experiments to confirm the subjective complaint of cramp. It was shown that cramp usually followed voluntary contraction of the muscle, but, as pointed out by Talbott, it could be brought on by faradic stimulation. The stimulus had to be repeated several times in rapid succession and to be of moderately high intensity applied at the motor point. Cramp could not be induced, either by voluntary contraction or by faradic stimulations, unless the muscle was allowed to shorten or was already shortened.

LE I—SUMMARY OF EXPERIMENTS ON W. S. S. L. IN WHICH BALANCES WERE KEPT

In 10 of the tests on the "cramp" subject, and on other occasions on other subjects, blood samples were taken before and after exposure to the heat, to estimate the chloride content of the blood and of the plasma (Ladell 1949). By applying the formula of Elkinton and Winkler (1944) to the water and salt balances and to the changes in the plasma chloride, it was shown that when salt was not replaced there was a flow of body water from the extracellular into the intracellular compartments, giving rise to intracellular overhydration: but when salt was replaced this did not occur (see table II).

When a severely salt-deficient subject did not develop cramp, he usually became puffy and œdematous towards the end of his exposure to the heat, suggesting that water was retained extracellularly, and that the intracellular fluid had not been diluted. A similar puffiness was seen in those who received large intramuscular injections of DOCA (desoxycorticosterone acetate) (Ladell 1945b). Though DOCA reduced the chloride losses in the sweat, the subjects were still able to incur considerable negative salt balances, yet none of them, even the cramp-susceptible, developed cramp when under the influence of DOCA. Subjectively, after DOCA, men felt better able to work in the heat and less tired than usual; they also felt fitter on those occasions when, without DOCA, they were overhydrated and under-salted but did not get cramp. We were unable to demonstrate objectively this improved ability to work after DOCA or in the "failed cramp" tests.

RELIEF OF CRAMP BY CHLORIDE

Clinically it is well known that heat cramp may be promptly relieved by giving salt. The following experiment showed that this relief is very rapid.

The cramp-susceptible subject exercised in the heat (dry-bulb temp. 100°F, wet-bulb temp. 94°F) for 120 min. He sweated 4720 ml., losing in his sweat 20·84 g. chloride as sodium chloride. He had been allowed to drink, and his negative water balance was only 1276 ml., but no salt had been replaced. At the end of the 120 min. he was complaining of cramp in both calves and in both thighs.

A pneumatic tourniquet was then placed above the right knee and inflated to a pressure of 250 mm. Hg, when pulsations in the dorsalis pedis artery on that side were no longer palpable. (Control experiments had shown that vascular occlusion for periods up to 35 min. did not itself bring on cramp in a subject not already exhibiting it.) The tourniquet was left in position inflated for 33 min. After 25 min. of vascular occlusion cramps could still be produced by voluntary contraction and demonstrated objectively even though the leg had become numb. After another 8 min.—just before the tourniquet was released—there was a loss of appreciation of pinprick over the toes and dorsum of the foot, and abnormal sensation up to the junction of the upper and middle thirds of the lower leg. By this time voluntary contraction was no longer possible, but electrical stimulation of the shortened muscle gave rise to a sensation of cramp, which could not be confirmed objectively.

At a time when the tourniquet had been in position and inflated for 15 min., and while cramps were present in both legs, 162 ml. of 15% sodium chloride solution, sufficient to cover the estimated salt loss, was injected into the right basilic vein over a period of $3^1/_2$ min. After the injection was completed efforts were made to induce cramp in both legs. From 2 min. after the end of the injection cramp could not be detected in the left calf, either subjectively or objectively; but, as already related, it was detectable in the right, occluded, leg for a further 7 min. It disappeared from the right leg 3 min. after the occlusion was released.

During this experiment, blood samples were taken before and immediately after exposure to the heat, and immediately before and after injection of the saline; the chloride contents of the whole blood and of the plasma from these samples were estimated and the changes in the fluid distribution in the course of the test calculated. The results, given in table III, show that the cramp was relieved when there was still some overhydration of the intracellular spaces.

DISCUSSION

This work suggests that two main factors are involved in the causation of heat cramp.

Cramp occurs when there is intracellular overhydration, similar to the overhydration observed by Danowski et al. (1946) in salt-deficient dogs which developed the convulsions of water intoxication. Generalised overhydration, however, does not necessarily cause cramp; this was shown by those tests in which subjects were treated with DOCA and could not develop cramp, and also on those occasions when the subjects had drunk large quantities of water, had taken no salt, but did not complain of cramp. If heat cramps in man are analogous to the convulsions of water intoxication in animals, these observations are comparable with those by Liling and Gaunt (1945) that suprarenal cortical hormones protect against water intoxication in animals. Moreira et al. (1945) showed that a natural cortical hormone reduces the chloride losses in the sweat, and this has also been reported for DOCA (Ladell 1945b); so the occasional non-susceptibility of subjects in negative salt balance and generally overhydrated might be due to increased activity (for some reason) of the suprarenal cortex, resulting in a saving of chloride, and giving this hypothetical protection. A possible mode of action of the cortical hormones might be the slowing down of the fluid transfer from extracellular to intracellular spaces that takes place when there is salt deficiency underhydration. That accumulation of extrac fluid does occur after the administration of DOCA i known and is shown by the œdema that dev (cf. Ladell 1945b).

The second important factor is chloride loss, absolute or relative. Cramp has not been observed the blood and plasma chloride contents have not reduced, or when the salt losses have been made g The suppression of diuresis that occurs in some su on exposure to the heat (Weiner 1945) tends to the relative salt loss, especially when the chloride co of the sweat is high. In the experiments described a man might lose 2 litres of sweat containing 0· NaCl; he would thus have a negative chloride b of 9 g. As this amount of sodium chloride is cont in 1·5 litres of body water, his water deficiency (rel to sodium chloride) would be only 0·5 litre, and as as he drank and retained more than this amount of he would dilute his body fluid. The relief of cr following the restoration of the blood and pl chloride to the normal level by the injection of conc trated saline was very rapid and complete, even tho intracellular overhydration apparently persisted; possibly sodium chloride has a specific effect on cram

Unless there is both intracellular overhydration a diminution in the chloride content of the tissue cramp does not occur. Usually the former is the of the latter, so the two are associated; but when they are dissociated cramps are not found. Such dissociation was seen after DOCA and in the experiment for the rapid relief of cramp. Clinically also there may be a lowered plasma chloride without cramp, as in type II heat exhaustion, when the mean plasma chloride was 86·8 m.eq. per litre. Taylor (1944) also depleted subjects of salt but none developed cramp; his depletions not, however, extreme, but only to a mean level, in plasma, of 96 m.eq. per litre.

Subsidiary factors in heat cramps, as pointed out Moss and others, are fatigue and acclimatisation. muscle may go into cramp, but the fatigued muscle more susceptible. The acclimatised individual is le liable to cramp, first because he is less easily fatigued; secondly because the salt losses in his sweat are le (Ladell 1945a, Conn et al. 1946), and hence, for the same work and exposure, the diminution in plasma chloride less; and thirdly because the muscles themselves appear to become more tolerant of cramp-producing conditions. An intensity of fatigue and amount of salt loss sufficient to induce severe cramp in a man when unacclimatised will induce only very mild indications of cramp in the same man when he is fully acclimatised. In view of the subjective improvement in performance after DOCA this may be another manifestation of suprarenal cortical activity.

all in the plasma chloride makes muscles susceptible amp. When the blood-supply to a muscle mass was ded the restoration of the chloride content of the elsewhere did not affect the cramp in the occluded le; thus the initiation of cramp is probably local peripheral. But Dawson (personal communication) suggested that the actual development of cramp ads on the integrity of the spinal reflex arc.

SUMMARY

ere is an analogy between heat cramp in man and r intoxication in animals. Both occur when there racellular overhydration.

at cramp does not occur, however, unless at the time the chloride content of the body fluid is nished. This diminution need only be local.

ere is some evidence that the suprarenal cortical ione may protect against heat cramp.

PHYXIA AND SHOCK IN THE NEWBORN

A. D. TELFORD GOVAN
M.B. Glasg., Ph.D. Birm., F.R.F.P.S.
DIRECTOR, RESEARCH DEPARTMENT, GLASGOW ROYAL MATERNITY AND WOMEN'S HOSPITAL

ASPHYXIA neonatorum is one of the commonest causes stillbirth. Dunham (1932) and Tandy (1933) main- n that it is the dominant cause, and Macgregor (1946) orted that 37·2% of stillbirths in her series were due asphyxia.

Apparently no clear record of post-mortem findings in is condition has been published. Almost all articles the subject deal with statistics, with only fleeting ferences to the pathology. These brief references gest that the condition varies greatly in its mani- stations; asphyxia, so called, seems to arise in very ried circumstances and commonly with no evident lation to preceding events. It has been reported in nnexion with normal vertex deliveries, forceps deliveries, ternal and external version, cæsarean section, accidental æmorrhage, placenta prævia, hypertensive toxæmia. nd eclampsia—in fact every conceivable obstetric con- lition. Similarly, shock is seldom mentioned in relation o stillbirths, which is curious in view of the importance ttributed to birth injury. It is perhaps noteworthy hat, according to Baird (1942), in 1939 the Registrar-General for Scotland could find no satisfactory cause for death in 37% of all stillbirths.

MATERIAL

An attempt has been made to define the changes in stillbirth associated with shock and asphyxia. Over nine months about 400 necropsies were performed at the Glasgow Royal Maternity and Women's Hospital on cases of stillbirth and neonatal death. From these, 116 stillbirths have been selected. According to the post-mortem picture these appeared to form three distinct groups.

GROUP 1

In the first group, accounting for 30 of the 116 cases, the child most commonly presented at birth the appearances of asphyxia pallida. Often, however, there were irregular patches of slight cyanosis on the face and limbs.

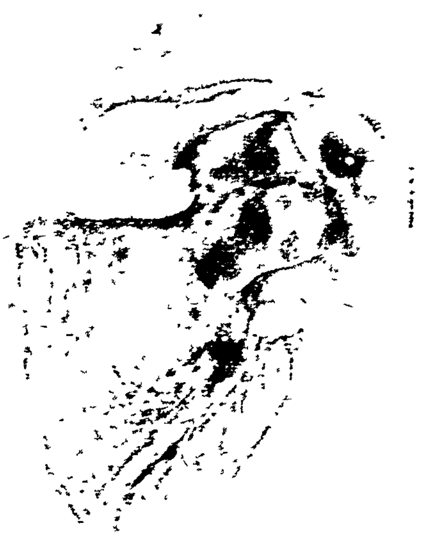

Fig. 1—Heart from a case in group 1, showing gross hæmorrhage along the atrioventricular sulcus and especially on the great vessels.

The pectoral muscles were usually pale, but occasionally they contained patches of hæmorrhage. In a few cases hæmorrhage was also found in the anterior mediastinal tissues and on the parietal pericardium.

The myocardium was commonly pale, but sometimes showed an irregular patchy congestion. In many of these cases, however, the most striking feature was hæmorrhage, forming a broad band along the atrioventricular sulcus on the posterior aspect of the heart, and commonly extending on the right side to the anterior surface and downwards along the coronary vessels to the apex. The coronary arteries were generally empty, but the accompanying veins were commonly distended with blood. In some cases hæmorrhage was more diffuse, arising in patches over the surface of the right ventricle. Hæmorrhages were also seen on the adventitial coat of the ascending aorta (fig. 1). Very little blood was found in the cavities of the heart. In a few cases tiny subendocardial hæmorrhages were found on the medial wall of the left ventricle a little below the aortic valve.

The thymus showed typical changes. It was always pale but often spotted with small round distinct hæmorrhages (fig. 2). The lungs were almost invariably cyanosed and had sometimes collapsed against the vertebral column. The pleural cavities frequently contained a little excess of fluid, and on the visceral surface there were numerous hæmorrhages in the form of either fairly large flame-shaped patches or a diffuse close-set rash of tiny petechiæ giving a rather "tabby-cat" appearance to the organ. Small hæmorrhages in the substance of the lungs were also common. Hæmorrhage was sometimes present beneath the parietal pleura on the diaphragmatic surface, and similar effusions of blood were found on the under surface of the diaphragm and along the ligamentum teres.

The liver parenchyma was usually rather pale, but in some cases there was subcapsular congestion with superficial hæmorrhages mainly on the upper surface.

The spleen was small, but showed little change on naked-eye examination, though in a very few cases intracapsular hæmorrhages similar to those on the liver were present.

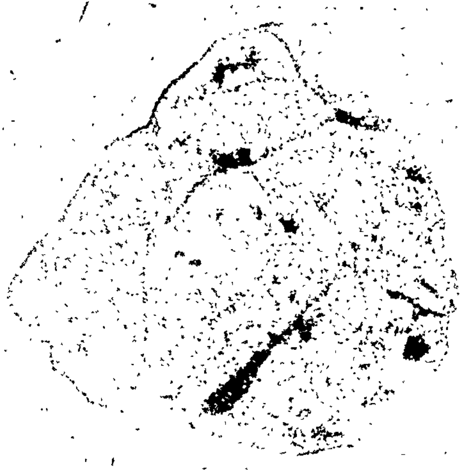

Fig. 2—Thymus from a case in group I, showing general pallor and discrete hæmorrhages.

The adrenal glands presented a variety of appearances. Most commonly the cortex was very pale brown and seemed to contain none of the usual yellow and rather refractile lipoid, while the medulla was grey. In a few cases capillary hæmorrhages were seen in the cortical tissue, while in others yellow lipoid was present as a thin subcapsular band and there was congestion of the deeper cortical zones.

A rather similar variation of the vascular pattern was found in the kidneys. Commonly there was generalised pallor of both cortex and medulla, but in many the medulla was relatively congested and the juxtamedullary zone of the cortex definitely so. In others tiny hæmorrhages were present just beneath the capsule.

Usually little change could be seen in the intestines or peritoneal cavity; in some cases there was a small excess of fluid, and in a very few there were petechial hæmorrhages on the serous surface of the bowel. The colon was distended with meconium.

The brain was usually pale and œdematous. Tentorial tears with varying amounts of subdural hæmorrhage were found in a third of the cases, but the hæmorrhage was severe in only a single case. Slight subarachnoid oozing over the cortex was found in 6% of cases. In most, however, no gross cerebral injury could be found.

Antepartum hæmorrhage, which occurred in 14 of the 30 cases in this group, appeared to be the most common associated factor. In 13 the hæmorrhage was accidental; in only 1 was it due to placenta prævia. In 9 cases there had been malpresentation, corrected by internal version, with delivery manually or by forceps. In another 7 the child was delivered by forceps, but in each instance the pregnancy was complicated by toxæmia. There were 8 premature births in this group; the post-mortem appearances did not vary from those already described.

GROUP 2

A very different appearance was presented by stillborn children of the second group. Here there was pronounced general cyanosis, with œdema of the face in some cases.

The pectoral muscles were congested, but there was no sign of hæmorrhage either in these or in the mediastinum. Congestion of the myocardium was extensive, but there was no epicardial hæmorrhage. The right side of the heart was usually engorged with blood, but otherwise the heart appeared normal.

In the thymus no gross abnormality, apart from congestion, was found.

The lungs were bulky and cyanosed. The lung substance was firm; the edges of the lobes were usually sharp, and fœtal lobulation was absent. Occasionally a few superficial petechiæ were found on the pleural surfaces.

There was severe congestion of the abdominal organs, including the liver, spleen, and kidneys. Hæmorrhage was infrequent, and the congestion was generalised—not confined to one part of the organ as in the first group. Thus in the kidneys both the cortex and medulla were congested, and indeed the cortex was the more congested of the two

The adrenals showed intense congestion of the
and inner cortex with occasional small hæmorrhages;
was reduced to a very thin and patchy layer just
capsule.

There was well-marked congestion of the brain
meninges. In about 40% of cases tentorial tears were
but hæmorrhage was not found in any significant
The vein of Galen was distended in every case but one,
the subdural hæmorrhage was a little more extensive.

Of the 24 cases in this group, death in 13 appeared
be due to an abnormality of the cord—such as
wound tightly several times round the neck, p
and compressed cord, and short cord with traction
throughout labour. In 5 death was due to oc
the trachea by aspirated vernix or meconium or
plug of mucus. In 6 there had been delayed labour
was allowed to proceed without interference; 2 of
were associated with malpresentation, while each
remaining 4 was the second of twins. Maternal to
was present in 5 cases, but did not appear to bear
direct relation to the cause of death. All of
babies were mature.

GROUP 3

Most of the cases (62) fell into the third group,
seemed to have features in common with both the
two. The child was always cyanosed at birth
occasionally had a petechial rash on the sk
often on the neck and chest.

Hæmorrhage into the anterior mediastinal tissues
common. The myocardium was patchily congested
pronounced distension of the veins. A band of h
similar to that seen in group 1 was present along the p
atrioventricular sulcus, extending anteriorly to the
ventricular line, and then passing down to the apex of
heart. Hæmorrhages were also present on the ascending
up to the reflection of the pericardium. The right side of
heart was usually distended with blood. In a few
subendocardial hæmorrhages were found in the left v

Punctate hæmorrhages were present on the thymus,
was grossly congested.

As in the other groups, the lungs were cyanosed. P
hæmorrhages, similar to those in the first group, were nu
ous. The lungs were bulky and firm and intrapu

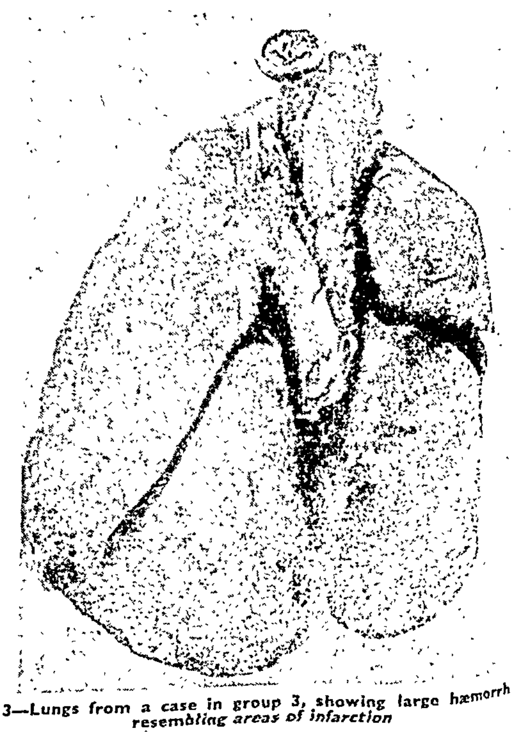

Fig. 3—Lungs from a case in group 3, showing large hæmorrh
resembling areas of infarction

rhages resembling infarcts were com- fig. 3). The air-passages sometimes ied a bloodstained discharge, which ry occasionally seen at the nostrils. eural cavities contained a little excess ous fluid, and there were hæmorrhages diaphragmatic surface.

liver was very congested, and hæmor- occurred in two forms: (1) commonly ge blood bullæ raising the capsule the underlying parenchyma, which ases had ruptured with a subsequent peritoneum: and (2) occasionally as use rash of petechial hæmorrhages th the capsule. Sometimes both types morrhage were seen.

capsular petechiæ were also found in pleen, and hæmorrhages in the splenic gave the organ a slightly nodular rance.

the adrenal glands medullary and rtical congestion associated with capil- hæmorrhage was pronounced, and in s an apoplectic appearance was evident. d appeared to be scanty or absent.

e kidneys were usually congested, but the congestion was ionally confined to the medulla and juxtamedullary ns; cortical hæmorrhages were common (fig. 4).

e intestines were congested and in a few cases petechiæ found on the serous surface of the small intestine. An s of straw-coloured fluid was present in the peritoneal y.

27 of the 62 cases there was no structural change in the or meninges. In all the cases the brain was very wet there was an excess of cerebrospinal fluid; many showed estion of the intracerebral vessels. Tentorial tears were ent in 20 cases; but in 12 of these hæmorrhage was nt, indicating that the tears had probably occurred post tem. This suggests that in this group tentorial tear is not rimary importance. In 9 instances subarachnoid hæmor- e occurred. This was always over the vertex: sometimes as diffuse, but commonly it took the form of small discrete e-shaped effusions from the superficial vessels. Gross aventricular hæmorrhage was found in 2 cases, and in a there were hæmorrhagic blebs beneath the ependyma on wall of the lateral ventricles. Of the remaining cases, ad been subjected to craniotomy and the 3rd was ncephalic.

n the mother the commonest complicating factor in s group was toxæmia, including eclampsia and acci- ital hæmorrhage; this arose in 54% of cases. Maternal ck was the next most common complication; in 20 es this was due to accidental hæmorrhage, in 5 to centa prævia, and in 2 to ruptured uterus. Eclampsia urred in 4 cases. Prolonged labour was often a ominent feature, but this was always associated with ne other factor such as toxæmia, antepartum hæmor- age, difficult forceps delivery, or cæsarean section. this group there were 16 premature babies, of whom weighed less than 4 lb. Prematurity, however, did t seem to influence the post-mortem appearances. In onatal deaths cerebral hæmorrhage appears to be rticularly associated with prematurity, but in this oup of stillbirths only 2 of the 9 cases with sub- achnoid hæmorrhage were born prematurely. Of the infants with hæmorrhage in or around the ventricles, was mature.

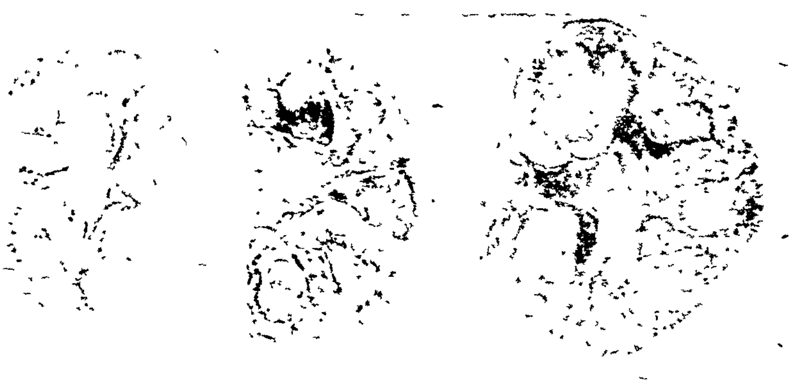

Fig. 4—Kidneys representative of the three groups. On the left is a kidney from a case in group 2, showing generalised congestion, especially marked in the cortex. The kidney in the centre is from a case in group 1, showing generalised pallor with relative congestion of the medulla. The kidney on the right is from group 3 and shows cortical hæmorrhages in addition to general congestion.

DISCUSSION

There seems little doubt that the cases of group 1 had uffered mainly from shock. The post-mortem appear- inces correspond to those described as the lesions of hock in adults and in animals.

Over fifty years ago Bardeen (1896) described hyper- æmia of internal organs, œdema of soft tissues, and petechiæ on serous surfaces in cases of severe burning. The appearances of clinical and experimental shock have been described in detail by Moon (1936, 1938, 1942a and b, 1944) and his associates. The changes they found consisted of somatic pallor, hyperæmia of internal organs, œdema, effusions into serous cavities, and hæmorrhages on serous surfaces. When death followed soon after the onset of shock the main changes were gross hyperæmia of internal organs and hæmorrhages, whereas when death was delayed for 24 hours œdema and serous effusions were prominent. Similar findings have been reported by Selye (1946).

In recent studies on shock special attention has been paid to the adrenals. Popják (1944) produced shock in rats by prolonged application of a tourniquet and found that the adrenals lost their yellow cortical lipoid and became greyish-brown. According to Selye (1937) this is typical of the initial stages of shock. It is significant that this was a common finding in group 1 of the present series. Moreover, subendocardial hæmorrhages were found in this group and according to Sheehan (1939, 1940) these are a reliable indicator of a shock-like condition, at least in obstetric cases. Similarly, Sheehan (1939) described intrapulmonary hæmorrhages in obstetric shock. Burt (1942) believes that asphyxia pallida is undoubtedly a condition of shock.

With regard to the second group, little comment can be made on the pathological findings. The picture is that of acute passive congestion, which may result from right-sided cardiac failure. The expanded lung suggests that an unavailing attempt at respiration has been made. The ultimate phase of de-oxygenation would undoubtedly lead to cardiac failure and thus cause venous congestion.

In the third group there appears to be a combination of asphyxia and shock. The widespread hæmorrhages suggest something more than passive congestion; and the hæmorrhages were found in the same sites as in group 1. Nevertheless, the peripheral cyanosis and the congestion of the spleen are not features of uncomplicated shock and correspond rather to the appearances in venous congestion in adults.

SUMMARY

The post-mortem appearances in 116 stillbirths are classified in three groups.

The appearances in group 1, where signs of asphyxia pallida were present at birth, correspond to those described in relation to shock in adults and experimental shock in animals.

The main feature in group 2 is acute venous congestion, which seems to be compatible with intra-uterine asphyxia.

In group 3 the findings suggest shock complicated by asphyxia or vice versa.

This classification may aid in the analysis of stillbirths, and it may be possible to assess the effect of obstetrical

abnormalities and of obstetrical manœuvres on the prognosis for the child.

FATAL ASPHYXIA FROM INTRATRACHEAL RUPTURE OF A TUBERCULOUS MEDIASTINAL LYMPH-GLAND

H. ANGELMAN
M.D. Lpool, M.R.C.P.
MEDICAL REGISTRAR, ROYAL LIVERPOOL CHILDREN'S HOSPITAL

W. M. L. TURNER
M.D. Lond., M.R.C.P.
CHIEF ASSISTANT, DEPARTMENT OF PÆDIATRICS, WEST LONDON HOSPITAL

OF the acute episodes that may punctuate the course of tuberculous intrathoracic infection in childhood, one of the rarest is asphyxia due to rupture of a caseous tuberculous lymph-gland into the trachea. In the case reported here we were present when the rupture took place.

CASE-RECORD

A boy, aged 6 years, was admitted to the Royal Liverpool Children's Hospital from the outpatient department with a history of cough, anorexia, and loss of weight. During the preceding three days he had complained of pleuritic pain in the right side of his chest and the cough had become worse. His development had been normal and he had not had any serious illnesses. There had been no known contact with any case of tuberculosis.

Examination and Treatment.—The boy looked pale and acutely ill, and his temperature was 101·4°F. Signs of consolidation were found over most of the right lung, and the spleen was just palpable. A chest radiograph showed consolidation of the lower part of the right lobe and the middle lobe, and partial consolidation of the lower lobe; the left lung appeared to be normal. White-cell count 14,500 per cmm. (polymorphs 84%, lymphocytes 13%); hæmoglobin 10·8 g. per 100 ml. (alkaline hæmatin method). He was given sulphadimidine ('Sulphamezathine') for a few days, without clinical improvement. A Mantoux test (1 in 10,000) proved positive, and he was regarded as a case of tuberculous consolidation of the right lung, probably associated with some pulmonary collapse though this was not demonstrable in the radiograph. Repeated gastric lavage did not reveal tubercle bacilli, and both culture and guineapig inoculation of gastric contents were negative. The cerebrospinal fluid was normal, and the corrected erythrocyte-sedimentation rate (E.S.R.) (Wintrobe) was 22 mm. in the first hour.

Progress.—After three weeks' rest in bed he seemed better: his appetite had returned; he had gained weight; and his cough was less troublesome. Further radiographs of the chest showed some extension of the consolidation in the right lower lobe, but later the shadows in the upper and lower lobes began to clear, the appearance of the middle lobe remaining unchanged; some thickening of the interlobar pleura could be seen. In none of the many radiographs could enlarged mediastinal glands be demonstrated.

After two months' treatment in the medical ward the patient's general condition had further improved and it was decided to transfer him to a convalescent hospital. There remained some impairment of the percussion-note over the right middle and lower lung zones, but air-entry was quite good; there had been practically no change in the radiographic appearance of his chest during his last month in hospital. The E.S.R. was still 21 mm., but the hæmoglobin had risen to 13 g. per 100 ml. Leucocytes now numbered 10,000 per c.mm. (polymorphs 60%, lymphocytes 32%).

Terminal Episode.—One morning, shortly before the was to be transferred, he stood up in bed, coughed, began to cry. He was extremely dyspnœic and became deeply cyanosed. His respirations were slow, and laboured, with prolonged inspiration and expiration, there was some wheezing. The ward nurse had noticed that morning that he had developed a short paroxysmal

On examination, breath sounds could be heard quite on the right side of the chest, but on the left side resonance had developed and breath sounds were To exclude spontaneous pneumothorax a needle was into the left pleural space—without result—and it evident that he had an acute obstructive emph. Rupture of a tuberculous gland into a main bronchus, ball-valve obstruction, was diagnosed tentatively. One (W. M. L. T.) passed a laryngoscope and noted that there no obstruction in the larynx; but it was impossible to duce a bronchoscope into the trachea owing to spasm vocal cords. All this time the child's condition was ext grave; he was grossly cyanosed and his pulse and resp were feeble. At one point he stopped breathing an pulse could not be felt, but he recovered for a time af injection of nikethamide. For a brief period he was with his head down to see whether this would dislodge obstruction; but it made no difference. The patient 15–20 minutes after the start of the attack, during oxygen had been administered continuously.

Necropsy.—A caseous mediastinal lymph-gland about 1$^{1}/$ in diameter had ulcerated through the right anterola aspect of the trachea about $^{1}/_{2}$ in. above the bifurcation. firm piece of caseous material, measuring $^{3}/_{4}$ in. in di lay across the openings of both main bronchi, compl obstructing them. The middle lobe of the right lung collapsed and showed caseous pneumonia throughout. right lower lobe showed tuberculous cuffing of the bronchi with a patch of tuberculous pneumonia at the base. The lung was distended and showed well-marked emphyse peribronchial caseation was evident near the root. Mi scopical examination confirmed that the disease was tu culous and showed emphysematous changes in the left l The right ventricle of the heart was dilated, but other o showed no abnormality.

DISCUSSION

Very few similar cases have been reported in the p twenty years.

Pichon and Cathier (1928) described acute asphyxia due intratracheal rupture of a caseous gland in a previou healthy child, aged 2$^{1}/_{2}$ years; at necropsy the trach was found to be completely obstructed by a firm case mass extruded from a tuberculous lymph-gland which h perforated the right lateral aspect of the trachea just abo the bifurcation.

Culotta (1930) reported the case of a child aged 4 yea previously healthy, who suddenly developed severe cyano with dyspnœa most marked on expiration. Necropsy revea complete tracheal obstruction by caseous material from lymph-gland which had ruptured into the anterolateral aspe of the trachea immediately above the bifurcation.

Scandroglio (1945) described the case of a boy, aged 3 yea whose symptoms included increasingly severe attacks dyspnœa and paroxysmal cough. When the tracheal ruptu took place there was a very severe asthma-like attack whic ended fatally. At necropsy, in addition to a small perforati of the bronchial wall which had occurred some time befo death, there was a wide perforation of the trachea, which w completely occluded by caseous material.

Lowys et al. (1948) reported a case of tracheal perforatio in a boy, aged 9 years, in whom the hilar glands were much enlarged. He died from asphyxia ten minutes after the onset of a sudden fit of coughing. At autopsy the lower part of the trachea and both main bronchi were filled with pus which had issued through the right anterolateral aspect of the trachea from a caseous paratracheal lymph-gland; there was also a small tracheo-œsophageal fistula.

In the case described here, the right lung was exten sively infiltrated by the tuberculous process and wa probably of little use as a respiratory organ. Apparently the onset of acute obstructive emphysema in the left lung so reduced its aerating capacity that the boy died from anoxia. With regard to the treatment of this emergency, the older reports emphasise the value of heotomy with suction, and perhaps we should have l this treatment when bronchoscopy proved difficult. e is the limiting factor. and it is unlikely that the ruction could have been removed quickly enough to the boy's life. Very vigorous percussion of the t with the child inverted might have dislodged the ruction and given more time to prepare him for ıchoscopy.

hile rupture into the trachea is rare. perforation he bronchi by caseating glands is comparatively mon.

boy, aged 22 months. was recently admitted in a state phyxia to the Alder Hey Children's Hospital, Liverpool. ıad had a cough nine months. and on admission he was osed and extremely distressed. with stridulous respira- Tracheotomy was quickly performed. but the child almost immediately afterwards. Necropsy revealed that hild had miliary tuberculosis: a caseous hilar gland had rated the right main bronchus just below the bifurcation e trachea, and a piece of caseous material lay blocking rachea a short distance above the bifurcation. Confluent rculous bronchopneumonia was present in the upper lobe e right lung.

1934 Scobie reported the case of a boy. aged 16 ths, in whom the rupture of a caseous mediastinal d through the right main bronchus near the bifur- on was successfully treated by tracheotomy and ion. Scobie found references to 94 cases of rupture aseous glands into the tracheobronchial tree. all in lren under the age of 13 years: 20 cases. including own, had recovered; of these 4 had coughed up the ous débris, while in 15 tracheotomy had been per- ed with suction or forceps to remove the obstruction 1 had been successfully treated by bronchoscopy. gényi-Göttche and Kassay (1947) found bronchial oration by caseous glands in 47·1% of necropsies on l cases of primary tuberculosis in children. Dufourt Mounier-Kuhn (1947) state that small bronchial orations in primary tuberculosis produce a typical ographic appearance—a finely nodular. partly con- t infiltration extending outwards from the hilum e lung and not quite reaching the periphery.

erforation of the trachea and main bronchi by caseous lymph-glands appears to occur predominantly on right side. The primary focus is commonest in the r lobe of the right lung. but this predominance may ue to the anatomical arrangement of the mediastinal ph-glands.

eports differ with regard to the effect of streptomycin nlarged mediastinal glands in primary tuberculosis. view of the satisfactory response of tuberculous bronchitis in adults, streptomycin may well prove ul in ulceration and perforation of the tracheo- ıchial tree in children with primary tuberculous tion.

SUMMARY

fatal case of perforation of the trachea by a caseous lymph-gland in a child is described.

racheal perforation by caseous lymph-glands is rare ng tuberculous intrathoracic infection in childhood, reas bronchial perforation is comparatively common.

anks are due to Dr. R. W. Brookfield for permission to ish this case. and for his assistance in preparing the paper: rof. Norman B. Capon for helpful criticism; to Dr. D. B. man and Dr. E. G. Hall for pathological reports; and r. Nora Walker for the radiographic reports. We also k Dr. W. E. Crosbie, medical superintendent of Alder Hospital, for permission to mention his case. and Dr. l. Todd for information.

Reviews of Books

Operative Surgery

FREDERICK C. HILL, M.D., associate professor of surgery, Creighton University, Omaha. London: Oxford University Press. 1949. Pp. 698. 63*s*.

THIS book covers the field of the general surgeon. and Dr. Hill describes in it the operations which he has found to be most satisfactory. "Designed for the intern. resident and less experienced surgeon," it is simple and uniform in presentation, and the operations selected are on the whole good and those usually practised in this country. But seeing the objects he had in view Dr. Hill could and should have given the young surgeon more practical hints on how to overcome the many difficulties which confront him. Division of the lienorenal ligament as a first step makes removal of the spleen much easier: the prevertebral fascia must be cut through to expose the phrenic nerve lying on the scalenus anterior: the peritoneum on the under surface of the diaphragm must be divided before the œsophagus can be brought down: the best place to enter an appendix abscess is in the gutter to the lateral side of the cæcum. These are the kinds of thing which the novitiate surgeon finds so useful, and it is in these that the book is rather wanting. Moreover the uninitiated reader is likely to get his values wrong in reading it. He could never guess, from the accounts given here. how tedious is the dissection for excision of the duodenum for ulcer, or what difficulties (not even mentioned) the portal vein presents when the head of the pancreas is being excised. Modern methods of closing the bladder after prostatectomy are not described. and the instructions for removing a calculus from the lower end of the ureter are meagre in the extreme. Though there is much good in this book—and though it is beautifully produced—it does not seem to have reached its object of being a real help to the young surgeon.

Psychological Aspects of Clinical Medicine

STEPHEN BARTON HALL, M.D., D.P.M., psychiatrist, Liverpool Royal Infirmary. London: H. K. Lewis. 1949. Pp. 416. 21*s*.

Psychosomatic Medicine

The Clinical Application of Psychopathology to General Medical Problems. (2nd ed.) EDWARD WEISS, M.D., professor of clinical medicine. Temple University. Philadelphia: O. SPURGEON ENGLISH, M.D., *professor of* psychiatry in the university. Philadelphia and London: W. B. Saunders. 1949. Pp. 803. 47*s*. 6*d*.

SLOWLY and almost imperceptibly the concept of psychosomatic medicine has gained ground in this country. But, while nobody will seriously dispute Plato's dictum that "it is the greatest error of our day that physicians separate the soul from the body," opinions are still divided as to what extent and in what manner emotional factors play a relevant part in the ætiology of disease.

In Dr. Barton Hall's book, written around a series of lectures for final-year medical students and postgraduates at Liverpool University, psychological medicine is integrated with general medicine, and psychological factors. be they emotional or intellectual, are stressed in relation to structural diseases. He deals discursively with emotional and intellectual development. psychometry. and the psychoses, neuroses. and psychopathies. and then with specific psychosomatic disorders, including effort syndrome, peptic ulcer, colon neuroses, asthma. skin diseases. rheumatism. and tuberculosis. The later chapters cover personality disorders. and abnormal behaviour as a symptom of physical disease—as for example in the epilepsies. chorea, meningitis, epidemic encephalitis. head injuries. and the dementias. A comprehensive survey of modern psychiatric treatment completes a readable book in which abstruse theories and dogmas are avoided. and debatable psychosomatic problems are rightly left for future research.

The revised edition of *Psychosomatic Medicine* describes the general aspects and the special applications to general medicine and the specialties of the concept of psychosomatic disease. The chapters on personality development and psychopathology, and on psychosomatic diagnosis, are particularly instructive for the interested but uninitiated reader. It might well serve as a reference work to supplement other reading, for it is not a book to be read from cover to cover. Professor Weiss and Professor English succeed in putting across to a medical public untrained in psycho-analytical theory the important discoveries which have been made in this field by research-workers and psycho-analysts; and anybody who wants to look up any specific psychosomatic subject—be it effort syndrome, peptic ulcer, skin disorders, or the psychological aspects of dentistry—will find useful information.

Sexual Behaviour, Normal and Abnormal

Dr. Eustace Chesser. London: Medical Publications Ltd. *1949. Pp. 220. 21s.*

In books on sexual behaviour the taxonomy of Krafft-Ebing dies very hard, and the study of the classical textbooks aggravates the alarm and despondency of patients who find their impulses classified. Most atypical patterns of sexual behaviour represent an equilibrium between "basic mammalian patterns," which are physiological *and general, and various degrees of personality* disorder; and the importance of most such deviations is entirely confined to the guilt, alarm, and distaste which they produce in the patient and his circle. The main task of sexual education in dealing with deviant behaviour of all kinds is, at the moment, to deflate the emotional currency of the whole subject to a level at which intelligent discussion is possible. Dr. Chesser attempts this task with some success: he is considerably more aware of recent work on human sexual physiology and psychology than many sex educators, and though one or two of his generalisations about psychogenesis and treatment *might meet with fairly widespread dissent, especially* among strict Freudians, the readers who will profit most from the book are unlikely to challenge him. His approach to deviation, from the practitioner's point of view, is a sound one: where it is a handicap, or part of a major personality disorder, seek psychiatric advice; otherwise disregard it. Far too many people with minor deviations appear in the divorce-courts or develop neuroses, and to both these tendencies undesirably solemn or taxonomic textbooks minister. If Dr. Chesser's book, which is suitable for the social worker, the busier doctor, or the intelligent general reader, marks another step in the extension of common sense into a contentious and alarming field of psychiatry it will be most welcome.

Aviation Medicine

Its Theory and Application. Kenneth G. Bergin, M.A., M.D., A.F.AE.S., British Overseas Airways Corporation, *sometime wing-commander,* R.A.F.V.R. Bristol: John Wright & Sons. 1949. Pp. 447. 35*s.*

An up-to-date review of this subject, with an account of the work done for the Royal Air Force during the late war, has long been wanted by those interested in aviation medicine. Dr. Bergin aims, he says, at presenting to the medical profession a brief review, in readable and compact form, of the physiological, medical, psychological, and epidemiological problems associated with aviation. This calls for great discrimination, because such a review, if it is to succeed, must also be well balanced and accurate. His book fails because it is not well planned and not always accurate and carries much needless repetition. The problem of cold, for example, could have been dealt with in a single chapter; instead, the information is scattered through four widely separated chapters. A whole chapter is devoted to the effects of alcohol on man, but the fundamental work done in flight to investigate the effects of centrifugal force on pilots is dismissed in two sentences; while the physiological principles involved in the emergency ejection of a pilot from his aircraft by the use of an explosive charge are not discussed at all. The writer of a textbook must discriminate between the relative values of available information. Dr. Bergin does not mention death due to anoxia, or the fatalities caused by decompression sickness and their significance—though he finds space to note that "the nicotine content of tobacco varies with the seed, soil, fertilizer and methods of harvesting curing," and that "pregnancy is not an illness but physiological state." This disappointing book is fusely illustrated, but some of the photographs misleading and many of the diagrams require explanation.

El diagnostico del embarazo con batracios machos

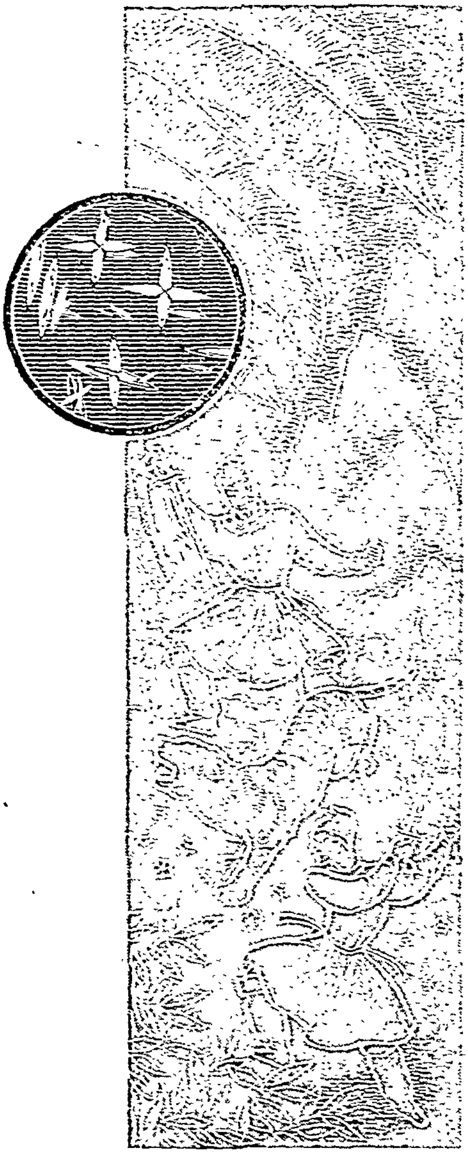
Carlos Galli Mainini, physician to the end diseases service, Rivadavia Hospital, Buenos
Buenos Aires: Artecnica Impaglione. 1948. Pp. l
m. $ n. 35.

This is a simple and practical monograph on the biological test for pregnancy using male batrac (toads and frogs) which the author introduced two years ago. Much of the subject matter has a been published—almost all of it in Portuguese or Spa He now presents this in a compact form with full description of his own methods and results. experimental and diagnostic data are given. It is for European readers to remember that Galli Main work has been on South American toads. Should t carry out similar work on European frogs and toa *and equally useful results are to be expected*—they m make corrections for dosage to allow for the size of the European anura. Besides 11 tables th are 22 illustrations, photographs, and drawings. photomicrographs are not well reproduced.

Human Helminthology (3rd ed. London: He Kimpton. 1949. Pp. 744. £2 10*s.*).—In Prof. Ernest Car Faust's informative textbook, the worms return with a we of new detail, collected for the most part during the war doctors who had the care of troops in tropical countries. T text has been revised completely, and is well illustrated wi photographs, photomicrographs, and diagrams. Empha falls more strongly perhaps on the zoological than on th clinical aspect of the subject, but both are covered. In a case those who essay to destroy these parasites must be by becoming familiar with their home life.

Hale-White's Materia Medica (28th ed. Londo J. & A. Churchill. 1949. Pp. 532. 16*s.*).—*Dr. A.* Douthwaite and the publishers have done well to rev *"Halo-White" so thoroughly,* in view of the many chan necessitated by the appearance of the *British Pharmacop 1948.* There will certainly be a large demand for this famil work. The contents might well be rearranged so as to gro the drugs affecting the autonomic nervous system together a measure which medical students striving to unders their pharmacology would appreciate. The analeptics, to might be assembled in one place, nikethamide and lep being removed from their isolation between camphor menthol. But the needs of the ordinary medical reader for textbook embodying recent *changes and* recent advances brief have been well met, and as usual the standard production is high.

Britannica Book of the Year, 1949 (London: Encyclo pædia Britannica Ltd. 1949. Pp. 712. £2 10*s.*).—In th course of ten years' hibernation this monster has becom almost fabulous; but here it is again as fine as ever. Th purpose of these yearbooks is to give a summary of wor events of the preceding year; and in this volume Walte Yust—with the able assistance of William Clark and a tea of distinguished contributors whose names in small type fi nine quarto pages—spreads the panorama before us. Many articles deal with medicine, ranging from such recent aspects as the start of the health service, psychosomatic disorders and the discovery of new drugs and remedies, to such hardy stand-bys as the drug traffic, accidents, and the common cold Individual diseases and disabilities which have a general or social interest also have been given a place, including tuberc losis, diabetes, arthritis, poliomyelitis, and deafness. But in *1948 there were plenty of events* besides those of medical interest, and the book has plenty to say about them, beginning with the coronation of Abdullah-Ibn-Hussein as King of Transjordan, and ending with the appointment of Gideon Brand van Zyl to the governor-generalship of the Union of South Africa. Good photographs illustrate many of the articles. Altogether this is just the Christmas pre-ent for those who find solace in current—or near-current—affairs



WHERE A POTENT HAEMATINIC IS VITAL

Where macrocytic anæmias call for prompt action physicians can rely upon FOLVITE, Folic Acid, Lederle, as a potent hæmatinic. FOLVITE rapidly restores normal red cell development and maturation — a fundamental factor in the successful treatment of macrocytic anæmias. [In true pernicious anæmia probably the treatment of choice is FOLVITE' with a potent liver extract.]

Folvite **BRAND OF FOLIC ACID**

REGD. TRADE MARK

The ancient Chinese tradition that warriors who ate the liver of the tiger were imbued with that animal's strength suggests that perhaps even early civilizations appreciated in some vague way the hæmatopoietic and vitamin content of liver.

In parenteral solution of 15 mgm./cc; tablets of 5 mgm.; and as an elixir containing 5 mgm. in each teaspoonful (4 cc.)

LEDERLE LABORATORIES DIVISION

Cyanamid Products Ltd

BRETTENHAM HOUSE, LANCASTER PLACE LONDON, W.C.2.

'GENATOSAN'

COLOURLESS TAR CREAM

('Genatosan' Dermatological Cream No. 19)

FORMULA w/w, *Phenol* 0·05%, *Pyridine* 0·025% *Toluene* 0·10%, *Naphthalene* 0·60%, *o-Cresol* 0·05%, *Carbazole* 0·125%, *Anthracene* 0·05%, *Phenanthrene* 0·20%, *Quinoline* 0·025%, *a Picoline* 0·025%, *Xylene* 0·05%, *'Genatosan' Base* 98·8%

CONTAINS the active principles of coal tar in an emulsified ointment base, but is free from the irritant and inert substances which are present in black tar.

The product is clean in use, will not cause irritation, and is particularly effective as an antipruritic and antiseptic.

Indicated for pruritus, prurigo, neurodermatitis, lichenification, infantile and chronic eczema, psoriasis and for all other conditions where tar therapy is of value.

A 'Genatosan' Product

Further information available on request.

PREGNAVITE

a single* supplement for safer pregnancy

CLINICAL USES

To improve the nutritional state where circumstances prevent consumption of all the protective foods required; to prevent hypochromic anæmia. Indications in the history of previous pregnancies: toxæmia, previous premature births, inability to breast feed and dental caries.

* The recommended daily dose provides: vitamin A 2,000 i.u., vitamin D 300 i.u., vitamin B_1 0.6 mg., vitamin C 20 mg., vitamin E 1 mg., nicotinamide 25 mg., calc. phosph. 480 mg., ferr. sulph. exsic. 204 mg., iodine, manganese, copper, not less than 10 p.p.m. each.

Hospital Costs

the last decade the cost of maintaining a patient ɔspital has increased alarmingly. The records ing Edward's Hospital Fund for London show among 159 voluntary hospitals the average ly cost for an occupied bed rose from £3 19*s.* 7*d.* '38 to £8 12*s.* 8*d.* in 1946 and £11 4*s.* in 1947; :he rise continues. In other lands it is equalled possibly surpassed. In Sweden, for example, tal costs in 1948 were about three times those in : and the weekly cost of maintenance in the ge general hospital, before devaluation, was t £12.[1] In the U.S.A. the national average cost lay of short-stay patients went from $8·60 in to $13·09 in 1948; and in *one* State the average per day in 1948 was almost double what it was 45.[2] The rise may, of course, be explained in us ways; but, discounting the change in the of money, the principal factors are probably delayed adjustment of the hospital to its environand (2) an intensification of internal pressure from ospital, reflecting the advance of medicine.

adjustment to changing social circumstances ıeant an overhaul of remuneration and hours of of all grades of hospital staff, and has at the same required the hospitals to alter their simpler century methods of handling patients. Thus verhaul of hospital catering and the introduction ɔpointments for outpatients lead to increased ıditure. The demand for such an adjustment n important, though largely unconscious, element pressure for a National Health Service, and it l be unfortunate if "economies" were now to be which curtailed this desirable process. A prere halt would certainly bring a host of troubles train; one would have to expect persistent ılty in the recruitment of staff of the right 'e, and constantly bad relations between the tal services and a public impatient of obsolete ptions of comfort and convenience. This adjusthas in these post-war years made a good ning; but it is only a beginning, and a perceptible er increase in expenditure will be needed before ı be said to be complete.

e intensification of the internal pressure reflecting lvance of medicine may yet cause an even greater ıse in the cost. For a long time now, and more ially since the great forward movement of cine began in the '80s and '90s of last century, nedical staff of almost every hospital has been ing for more." It is of the very essence of a good tal administration to find a means of handling pressure without blunting its edge. With limited rces the financial side cannot always say "yes" ery demand for additional facilities, and there o be some means of determining priorities and sing the strength of the relative claims. So as the hospital was the unit, as in the voluntary m of Great Britain and America, the mechanism h provided for discussion of priorities in the medical staff committee sufficed pretty well to sift the grain from the chaff and to allow of a controlled expansion. But several things have happened in recent years to make the problem more difficult and more complex; and part at least of the upward surge of expenditure now going on may be attributed to the weakening of this old machinery. The development of specialties has made it harder and harder for the medical men as a group to answer for the necessity of this or that; and now the change in the method of financing the hospital services has obscured the fundamental need to provide this cross-check of medical opinions against each other.

This is one of the strongest reasons not only for a strengthening, and a better understanding of the functions, of the medical staff committees in the hospitals, but also for a change-over to a system of round-sum allocations to each regional board and thence to each hospital management committee. Only so can we institute a system whereby at each important stage projects for increased expenditure have to run the gauntlet of medical criticism, and of competition with other more or less comparable medical needs, before ever they come before the lay committee. Matters must be so arranged—as they were in the old voluntary hospitals—that the doctors themselves prune the vigorous growth of the many-branching tree of the hospital service; for, if they do not do the pruning, some clumsy piece of political or administrative machinery must be invoked, which is as likely as not to cut away the fruit buds with the useless wood. Today the arrangements are weak at all three levels. In the hospital management committees the medical staff committees tend to be sidetracked when proposals for expenditure are under consideration, and their former status has actually been impaired by the appointment of medical men to the hospital management committees themselves. At the regional level the medical advisory committees seem to be preoccupied with medical staffing throughout the region, and have enjoyed something of a free hand in spending public money on appointments without having to weigh up this expenditure against other medically urgent needs. At the centre the Central Health Services Council has not, so far as we are aware, been afforded any data to enable it to form comparisons of this kind; and in any case it is probably not constituted in a way to permit it to perform such a function.

Nobody would suggest that the necessary modification of method will be easy; but unless a way can be found it will not be surprising if the internal pressure exerted, with the best of intentions, from the medical side gets more and more out of hand.

Amputations

THE ill wind of war at least blows good to the amputee by stimulating interest in the technique of amputation and in the making and fitting of artificial limbs. Since the first world war these last two tasks have largely been in the hands of the Limb-Fitting Service of the Ministry of Pensions, and under the N.H.S. this service has been extended to every amputee in the country. The advantages of such centralisation are obvious, and some of its results have lately been described by Dr. A. W. J. CRAFT.[1]

ırles, J. A. *Lancet*, Sept. 24, p. 571.
Amer. med. Ass. Sept. 10, p. 136; see *Lancet*, Oct. 8, p. 639.

[1] *Ann. roy. Coll. Surg. Engl.* 1949, 5, 190.

Each war produces a generation of surgeons who become only too familiar with amputation and soon learn what are the desiderata of a good stump according to the views of the time. But no surgeon does many amputations in peacetime, and Dr. CRAFT's plea that they should be the province of the orthopædic surgeon is probably sound. However, any surgeon may be called on to do an emergency amputation after injury; so all should know the requirements of the limb-fitter well enough not to leave him an entirely unsuitable stump to fit.

With antibiotics and the modern treatment of shock it is seldom that a definitive operation cannot be done at once, particularly if the technique of delayed primary suture be followed. The steadily mounting experience of the limb-fitters has shown that there are ideal levels which ensure the best control of the prosthesis with the least danger of later circulatory troubles in the stump: these are 10–12 inches of femur from the great trochanter, $4^1/_2$–5 inches of tibia, 8–9 inches of humerus, and 6–7 inches of radius and ulna. Disarticulations are usually bad—there is no room for the joint in the prosthesis—and in both hip and shoulder the preservation of a short stump of bone is helpful because it enables the patient to wear a tilting-table limb in the former and a more comfortable prosthesis in the latter. If one cannot preserve more than 5 inches of femur the patient is better off with a tilting-table limb, and the femur should be shortened to 2 inches below the great trochanter. Below the knee it *is* possible to fit a satisfactory limb with as little as $1^1/_2$ inches of tibia, but the longer the better up to 5 inches. (Stumps longer than this are liable to suffer from malnutrition of the soft parts.) Opinion with regard to Syme's amputation, adverse at the beginning of the late war, seems to be swinging back again; it is a popular operation across the Atlantic, where many examples can be seen giving no trouble after twenty years and more. There is no doubt that poor technique accounts for many of the cases requiring later amputation at a higher level.

To do an amputation well requires experience and judgment—it is not an operation to leave to the junior registrar without supervision. At all sites except the hip, shoulder, and ankle the scar should be transverse and lie posteriorly on the end of the stump, to avoid pressure against the socket. Above all it must be mobile, and this, as Prof. G. PERKINS has stressed, can best be ensured by careful suturing of the deep fascia across the bone end, the skin then remaining mobile on the fascia. In all types of artificial limb some "piston action" takes place between stump and socket, and it is the resultant drag on a scar adherent to bone that may lead to pain and breaking down of the wound. Bulky muscles should be trimmed back; nerves should be divided cleanly and otherwise left strictly alone—a neuroma will form whatever the surgeon does. No object is served by suturing the muscles across the bone end. By careful trimming of the flaps and accurate suturing a linear scar can and should be produced, and, as Dr. CRAFT points out, this is the time to do it. The necessity for a later soft-parts operation to cure the intertrigo of a puckered scar would not then arise so often. The preparation of the stump for the prosthesis must start as soon as the acute postopera pain is over; full mobility of the joint above sh be regained by the time the stitches are remo and correct bandaging and exercises start forth These simple points have all been stressed before, Dr. CRAFT tells us that they are not always atte to. In the patient's interests it behoves us not make the limb-fitting surgeon's task more diffic and this is particularly so in the case of chil where the careful follow-up at Roehampton exposed *many of the traps into which* we may Bones in children's stumps do not grow exactly we might expect from our knowledge of anato and physiology.

Malignancy: a Hypothesis

IF the ovaries of mice are removed at pube structural and functional differentiation of the bre does not take place. But if an œstrogen is appl to such mice the cells of the rudimentary bre undergo vigorous multiplication; the milk-du enlarge and grow into the stroma, glandular ac sprout from their blind ends, and secretion appe in their lumina. Stock mice vary widely in th response, but experimentalists *have found that* uniform maximum degree of cell multiplication be obtained by inbreeding œstrogen-sensitive strains. Using such a strain Dr. B. D. PULLINGER, of t Imperial Cancer Research Fund Laboratories, h shown that there is a true quantitative relation betwee the weight of œstrogen administered and the glandula differentiation and secretion produced. It is clearly permissible to regard œstrogen as a histospecific hormone, and it is impossible to escape the conclusion that this hormone, and the œstrogen-*like* steroids which produce an identical pharmacological respons have a powerful and specific effect on the gland cel of the breast, impelling their nuclei to mitosis an governing their functional differentiation.

In her Kettle lecture which we publish this wee Dr. PULLINGER describes the characters of the trans-plantable, naturally occurring, mammary adeno-carcinoma of mice. Careful examination by Profess PASSEY's team in Leeds has shown that the cells of some of these tumours do not contain the virus-lik milk-factor of Bittner; and it has also been demon-strated that such tumours *grafted into* spaye females, and even into males, will grow just as we in this œstrogen-free environment as in the intac female. The capacity of these virus-free tumours to grow in the absence of ovarian hormone is an arresting feature, and Dr. PULLINGER *devoted* much of he lecture to a closely reasoned discussion of its signifi-cance. The steps in her argument *may* be summarised as follows:

1. Biological evidence suggests that cell division i *more likely to be due to a positive* stimulus than to the absence or removal of *a* restraining influence.

2. In the breast at puberty, and during the non-*malignant phase which precedes the* development of mammary adenocarcinoma in mice, the stimulus to cell division is an ovarian hormone.

3. There is a close enough resemblance between th breast at puberty reacting to œstrogen and the func-tionally differentiated adenocarcinoma of mice to suggest *that in both of them growth and* differentiation are du to the same positive stimulus—i.e., an œstrogen.

If this is conceded, it is not improbable that the ; of the adenocarcinoma acquire the property of orating an œstrogen within their own substance. ; would explain not only the increased rate of cellular iferation of the tumour cells but also the functional entiation of the growth itself. Such differentiation er physiological conditions can only be produced by histospecific hormone of the ovary.

On this hypothesis the tumour cells in acquiring ignancy also acquire a new chemical property. ogeny provides enough evidence to suggest that which develop the capacity to synthesise a chemical stance transmit this capacity to their progeny in etuity.

r. **Pullinger** has submitted the relevant evidence areful and cautious scrutiny. It has led her to the nciation of a hypothesis which may very materially st our understanding of the cause of cancer. ideas would cease to be hypothetical if it could proved that mammary cancers themselves produce gnificant quantity of intracellular œstrogen. The would be of wide significance if it could be wn that prostatic cancers produce intracellular rogen and thyroid cancers intracellular thyrotropic mone. Dr. **Pullinger** believes that her suggesis could be put to the test of experiment but does underestimate the difficulties. She outlines an uous and rigid experimental programme. The othesis, as it stands, merits careful consideration ; founded on exact experiment and long experience.

Folic Acid and its Antagonists

HE idea that folic acid was the actual antinicious-anæmia liver factor had to be given up as n as it became clear that highly active purified liver racts contained no detectable folic acid. But the leniable fact remained that folic acid did transform characteristic megaloblastic hyperplasia to normostic, and, so far as could be seen, did it very comtely. **Bethell** and others [1] in America suggested t liver extracts acted by liberating free folic acid n the conjugated forms in which it exists in ural foodstuffs. Experiments and trials designed test this hypothesis have produced conflicting ılts ; the available evidence was lately summarised **Wilkinson** and **Israëls**,[2] who concluded that the othesis could no longer be sustained ; **Davidson**,[3] ever, takes the contrary view. Meanwhile, erican workers who are trying to find the link ween liver factor and folic acid have turned their ention to a different approach—by studying the ects of folic-acid antagonists.

hese substances, of which there are several, are mically very similar to folic acid (pteroylglutamic d) and prevent folic acid from acting as a growth tor for *Lactobacillus casei*. One of the most active them—aminopterin—has been used in the treatnt of acute leukæmia. **Innes** and others [4] studied action of some of these substances on blood mation in the guineapig ; they chose the guineapig ause, hæmatologically speaking, it resembles man re closely than do other rodents. Of the various tagonists tried, only aminopterin had any striking effect. They gave daily doses of 0·25–0·5 mg. of aminopterin over a long period, and these relatively large doses produced a slowly deepening anæmia and leucopenia ; the marrow however became hyperplastic because large numbers of primitive cells, identified as reticulum cells, appeared in place of the usual mature erythroblasts and myelocytes. If the drug was stopped recovery began within 24 hours : if it was given for long enough the animal died with severe anæmia, granulocytopenia, and sometimes hæmorrhage due to lack of blood-platelets as well. Neither liver extract nor folic acid itself could counteract the effect of the aminopterin. These experiments showed, at least, that folic-acid antagonists have a profound effect on hæmopoiesis, and the combination of primitive cell hyperplasia in the marrow with anæmia in the peripheral blood resembles the state of affairs seen in pernicious anæmia ; but it also resembles the findings in some leukæmias, and it is not easy to translate these guineapig results into terms of human disease. **Thiersch** and **Philips** [5] gave truly immense doses of aminopterin to dogs : either single doses of 5–56 mg./kg., or total doses of 0·3–0·8 mg./kg. spread over several days. It was not surprising that the animals developed violent and fatal symptoms ; they had diarrhœa that soon became bloody, they lost weight, became dehydrated, and died in coma. The bone-marrow became severely depleted, all elements being affected ; but in the small islands of hæmopoiesis that remained some erythroblasts were found with a nuclear structure resembling that of the human megaloblast, and forms intermediate between normoblasts and these megaloblast-like cells were detected ; in addition small numbers of giant metamyelocytes and hypersegmented polymorphs were found. They have thus some evidence that a drug which inhibits folic acid can produce changes in the erythroblasts and granulocytes not unlike those seen in human megaloblastic anæmias ; but again, it is difficult to compare this violent poisoning with any human syndrome. **Meyer**, **Ritz**, and others [6] have given folic-acid antagonists to 5 patients with pernicious anæmia. They mostly used 'Met-Fol-B' (methylpteroic acid), an antagonist that **Innes** et al. found to have no independent action in the guineapig. They noted that when a sufficient dose of folic-acid antagonist was given together with liver extract in therapeutic amounts, the expected rise of red cells and hæmoglobin in the blood did not occur ; reticulocytosis was repressed ; and megaloblasts remained in the bone-marrow—in other words, the remission that the liver should have caused was inhibited. Their patients suffered severely from toxic symptoms ; they were weak and ill and felt tired and sleepy. One patient became disoriented and unable to walk at a time when, in spite of the folic-acid antagonist, her hæmoglobin rose from 6 to 8 g. per 100 ml. Another became critically ill and was rescued only by immediate blood-transfusion. The impression given is that the patients were more ill than the average patient with uncomplicated pernicious anæmia of the same blood-level, and the depressant effect of the antagonist sometimes lasted as long as a month

after the last dose. Meyer et al. also reported results with one patient who was given vitamin B_{12} together with the folic-acid antagonist amethopterin; the results were similar—there was no remission, no reticulocyte response, and megaloblasts persisted in the marrow.

It is clear then, that folic-acid antagonists are, as a rule, very toxic substances, which, when given to animals, can depress or disturb the formation of all the blood-cells, and in human pernicious anæmia will cause the megaloblastosis to persist in spite of liver treatment that should reverse it. The toxicity of the drugs, however, makes it difficult to assess how far the changes induced are due to a non-specific depression of erythropoiesis and the formation of other blood-cells, and how far they are similar to human deficiency diseases. Meyer et al. interpret their results as showing that pteroylglutamic acid is necessary for the normal production of red blood-cells, and is presumably the real operative agent that transforms the pathological megaloblastic marrow the physiological normoblastic state. They apparently given up the conjugate-liberation hy thesis and quote with approval Jacobson's suggest that liver factor, and vitamin B_{12}, act by convert "free" folic acid to a "reduced" form. If this so, surely the next step is to prepare this "reduced folic acid and test it in patients with pernici anæmia in relapse. The results of this experiment a less dangerous one, we hope, than that with folic-a antagonists—should be instructive. For, if folic is of primary importance compared with liver fac and vitamin B_{12}, it has to be explained why so patients with pernicious anæmia relapse on treatment and why neurological relapses occur. There evidently some connexion between liver fact vitamin B_{12}, and folic acid, but more facts are clea needed before any acceptable hypothesis can worked out.

Annotations

WORLD TEMPERATURE AND THE FATE OF NATIONS

For many years now Dr. Clarence Mills, of the University of Cincinnati, has argued that human life and the fortunes of nations depend on the temperature of the portion of the earth they inhabit. As the hive is heated, so the creatures move; but with the difference that it is cold that moves them to activity and heat that stifles and chokes their ambitions and abilities. According to Mills,[1] after several weeks in a hot humid environment physical and mental activity decline, the secretions of thyroid, suprarenals, and gonads diminish, and initiative gives way to a desire for ease and security. The growth of children, he believes, is slowed, the onset of puberty is delayed, fertility is reduced, and resistance to infection is lessened. He attributes these effects to the difficulty of heat-loss in such an environment, *claiming that if the body cannot dissipate its waste heat,* the total combustion must be reduced accordingly.

There is evidence in favour of at least his main contentions. Some of it—perhaps the more convincing part—comes from the laboratory. The ability of rats to solve maze-tests is sharply reduced by keeping them in a hot moist climate, and their memory (i.e., power of retention of the solutions) is likewise depressed. Then fertility declines despite increased matings and the growth-rates are decreased. Evidence for the human is necessarily statistical, but Mills says that it supports his thesis. Conception-rates in the hot climate of Florida decline by 30% during the long summer heat, while in Maine, with temperatures like those of an English June, conceptions rise to their highest for the year. The results of conception are likewise influenced by the conditions under which it takes place. In the latitude of Cincinnati the children conceived during July and August have only half the chance of entering the university of those conceived in winter. They have less chance of appearing in *Who's Who.* As for Presidents of the United States, the present incumbent is the only August conception ever to have reached that office!

Mills goes further than this, and seeks to explain the history of peoples by the alleged changes in world temperature since the Ice Age. The days of Greece and Rome were in what he calls a cold millenium, the Dark Ages in a succeeding hot one. Today temperatures are moving irregularly upwards; the nations of t north will become the receivers of optimal temperat conditions. Coincidently the semitropical letha which (Mills believes) engulfed Greece and Rome, i creeping northwards over the United States and Centra Europe. Perhaps this part of the hypothesis is the most open to criticism—though also the most interestin He talks all too glibly of cycles, when the statistici knows that to establish the existence of a true cycle that is, a cycle that cannot be reasonably attribut to chance variations—is extraordinarily difficult. Mo of the so-called business cycles have little attraction wh viewed with the eye of probability theory, and Mills 2000-year cycles are frankly unsubstantiable by a known technique.

Here is one fascinating task for geographers a mathematicians. And on the other side, physiologi need to know far more of the effects of heat on the bod Intensive study developed during the late war, a continues to some extent, for practical reasons. B its theoretical importance may prove more than it initiators anticipated, if Mills is even partly right his opinions.

THE NOBEL PRIZEMEN

The Nobel prize for physiology and medicine has bee awarded jointly to Prof. Walter Rudolf Hess, of Zurich and Prof. Antonio Egas Moniz, of Lisbon.

Professor Hess has won fame by his experimenta physiological investigations of the diencephalon, employ-ing permanently inserted electrodes which allowed hi to observe the animals in conditions as natural possible. The results of his and his collaborators' work which has been going on for about three decades, hav been incorporated in a recent monograph on Da *Zwischenhirn.*[1] What must strike the reader of thi book, as well as of his numerous earlier publications are the high qualities of sustained purpose and of scientific accuracy with which he proceeded step by step to unravel the complexities of this brain centre. His main interest was in the localisation of autonomic function, but he also investigated the rôle of the diencephalon in the control of sleep, instincts, and emotion.

While Hess's studies have been made in the remote atmosphere of the laboratory, Moniz's work has been practical. Though his two contributions to medicine ar unconnected with each other—the one aiming at diag-nosis, the other at therapy—they have in common bol imagination. In 1927 Moniz (with Almeida Lima) intro-

---

[1] Hess, W. R. Das Zwischenhirn. Basle: Schwabe. 1949

·d cerebral angiography, which now holds, all over world, an important and undisputed place in the nosis of intracranial disease. His other contribution prefrontal leucotomy, which was first performed on uggestion by Lima in 1935, after he had attended econd International Neurological Congress in London listened to Fulton and Jacobsen's report on the t of frontal lobectomy upon the behaviour of npanzees.

iere is an extra significance (probably not unintended) is partnership. The frontal lobe and the diencephalon closely linked and are widely regarded as the pivot system of centres whose function may be the central lation of emotion, emotional expression, and per- lity make-up. That the work of the two men should been connected by the joint award might be rpreted as a recognition of the present tremendous ch. in psychiatry and neurophysiology, for a physical s of mental function and dysfunction.

THE EVOLUTION OF APES AND MEN

the fifth William Smith lecture, delivered before Geological Society of London on Oct. 19, Prof. E. Le Gros Clark, F.R.S., reviewed the contribution e by recent fossil discoveries to the problem of the ution of the Hominoidea—that is, the group of nates which includes Man and the anthropoid apes.

is now known, largely as the result of the energetic orations of L. S. B. Leakey, that in East Africa ng early Miocene times (probably 25–30 million s ago) primitive types of anthropoid apes flourished reat variety. Some of the smaller species, Limno- ecus, were evidently related (and may have been stral) to the modern gibbons. In their dentition showed marked similarities with other extinct on-like forms such as Propliopithecus and Pliopi- us. The latter have been known for some time from and teeth, but no remains of their limb skeleton e ever been found. Quite recently, Leakey made important discovery of some limb bones of the East can representatives of this group. These unique imens are now being carefully studied, and it is ady clear that, while they show certain hylobatine ures in their structural details, in the general limb portions, they had not yet developed the characteristic ialisations of the modern gibbons. The larger cene apes which were contemporaneous with Limno- ecus are now represented by very numerous remains aws and teeth, and also by a few limb bones. The er demonstrate that these types had also not yet eloped the brachiating specialisations which are mon to all the modern large apes. The skull of one he fossil large apes, *Proconsul africanus*, is of the test interest, for it is the only skull of a Miocene so far discovered. It shows a number of primi- features in which these early apes had hardly anced beyond the cercopithecoid level of evolutionary elopment.

eferring to the fossil "man-apes" (Australopithecinæ) n South Africa, the lecturer emphasised the great ntity of new material which has been discovered in last two years, consisting of many specimens far e complete than those previously known. In par- lar, the almost complete and undistorted adult skull overed by R. Broom at Sterkfontein in 1947 now mits more accurate comparative studies. An examina- n of some 400 adult ape skulls has shown that in a nber of characters the Australopithecine skull roaches Man much more closely than do any of the dern apes. This is made particularly clear by the parison of indices expressing the upward extension the nuchal area on the back of the skull, the total ght of the skull above the level of the orbits, and forward position of the occipital condyles. The fundamentally hominid characters of the Australopithecine dentition similarly find no parallel in the anthropoid apes. A survey of more than 150 immature skulls of modern apes, for example, makes it clear that in the latter the strikingly human characters of the milk dentition of the Australopithecinæ are in no case even closely approached. Indeed, it may now be stated that, while there are many basic features in which the dentition of the fossil "ape-men" depart widely from that of the anthropoid apes, there seem to be no really fundamental characters whereby it can be certainly distinguished from primitive hominids of the Pithecanthropus group (not even in the absolute size of the molar-premolar series). The hominid characters of the skull and dentition of the Australopithecinæ are matched by those of the pelvis discovered at Sterkfontein in close association with skulls and other parts of the skeleton of these extinct creatures. The pelvis is quite unlike that of the anthropoid apes and is fundamentally human in its general form. At the same time it shows certain peculiar features which distinguish it from modern types of Man.

Another Australopithecine pelvis discovered at Makapansgat (some 200 miles north of Sterkfontein) is also fundamentally human and reproduces the same unusual features which are distinctive of the Sterkfontein specimen. These new discoveries, taken in conjunction with the evidence of the skull and of other portions of the limb skeleton, appear firmly to establish the earlier inferences that the Australopithecinæ were capable of standing and walking in approximately human fashion.

All these comparative observations go far to substantiate the conclusions of Dart and Broom that the South African fossils represent a group of primitive hominoids which were at least closely allied to the precursors of Homo. In other words, it is hardly possible any longer to evade the conclusion that, in spite of the fact that they possessed a brain not much larger than that of a gorilla, they are to be classed as representatives of the hominid, rather than the anthropoid-ape, sequence of evolution.

A MOROSE MEETING

AT the annual conference of Representatives of Local Medical Committees on Oct. 27, the mood was anxious and subdued. The keynote speech came from Dr. S. Wand, chairman of the General Medical Services Committee, who declared: "We are fighting for more than money—we are fighting for status." It was with money and status that the meeting was mainly concerned. As to status, representatives were able to take some comfort from the Ministry of Health's recent circular[1] recommending that general practitioners should continue to have hospital beds at their disposal. But if the Ministry understands the importance of the general practitioner—and this circular is almost the first hint in eighteen months or more that it does—the public, it seems, do not; and their growing importunities led representatives to call for machinery to deal with complaints against patients, who, it was suggested, should be guided by a code of rules printed on their medical card.

The discussion on remuneration was inevitably overclouded by the economic situation. Indeed, one speaker proposed that the practitioner's claims should be fully met only "when the financial state of the country permits." "Who are we," he asked, "to place our services above those of all other sections of the community?" To which Dr. J. A. Ireland replied that this assumed a position that did not exist; for doctors differed from other workers in that no agreed rate had ever operated between them and the Ministry of Health. At what level the rate will—if ever—be agreed may depend partly on the results of the Ministry's investigation of present earnings, which the Minister himself said

---

1. See *Lancet*, Oct. 15, p. 703.

must be completed before any action was taken. Dr. Wand told the meeting that the contents of the report became known to the General Medical Services Committee last August: but the report's value had been disputed on the score that it disregarded recent compulsory reduction in lists of over 4000 and the position in partnerships where money paid to one partner was out of proportion to his share of the practice. The report was in fact "misleading and unreliable," and the Ministry was now redrafting the tables in it. The delay, which had now lasted many months, might almost be described as a Government weapon. "I for one," said Dr. Wand, "see no reason at all why we should not determine from July 5 what is the proper amount of money in the pool in the light of the Spens report." Later in the meeting Dr. Wand's unwontedly brusque reaction to claims made on behalf of rural practitioners suggested that the report at least makes clear that this group is faring better than was once believed. But the difficulties of the suburban and of some urban practitioners was disputed by none. Testimony was not lacking. For instance, Dr. P. Y. Lyle, of Southport, declared: "Ours is an over-doctored area, and 93% of the population is on the executive council's list. If we cannot secure retrospective improvement in remuneration, the position will be extraordinarily serious." Dr. W. D. Anderson spoke of smouldering resentment in Glasgow, where private practice was now almost non-existent: and Dr. H. B. Woodhouse, who seemed to favour withdrawal from the service if the practitioners' claim were not soon met, argued that doctors in industrial areas would be readier to support this action if only they realised that, were the claim denied, other doctors would flock into these industrial regions. In any event was it right—as figures had shown in respect of Glasgow and Manchester—that dentists and opticians should earn net incomes in excess of those earned by medical practitioners? The gloom was slightly lightened by Dr. Wand's announcement that the balance of the Special Inducement Fund, amounting to about £95,000, could now be used to help doctors who were in difficulty even if they did not work in an inducement area. It is proposed that grants shall be made on a limited and descending scale over a period of perhaps three years, to tide practitioners over transitional difficulties.

Turning to the matter of practice vacancies, representatives agreed that the delay in filling these is in the neighbourhood of three months, and several expressed disgust that local decisions had been overruled by the Medical Practices Committee. To this it was retorted that local executive councils had not always carried out their task of selection either thoroughly or objectively. Both sides were satisfied with a compromise motion proposing that when making an appointment the Medical Practices Committee should invite a representative of the local medical committee to attend for consultation. Among the further topics on which the representatives touched was the collection of the new Government charge on prescriptions. Dr. J. A. Pridham argued that, whoever collected the money, it should not be the doctor; and on behalf of rural practitioners who do their own dispensing Dr. J. C. Pearce roundly declared the scheme to be impracticable. Dr. A. Talbot Rogers felt that not only old-age pensioners but also people ill for more than a month should be exempted from the charge.

An Eastbourne motion calling for payment of a fee of not less than one guinea for the performance of circumcision drew from another representative the sardonic comment that if this were granted there would not be a foreskin left in the country. Representatives found it difficult to decide whether to meet next in June, when tired and bellicose, or in October, when fresh and resourceful. Finally they opted for October. Perhaps by this time next year [illegible]ore news for the conference: but, judging by the tone at this gathering, few dare hope that all the news will good.

MORPHINE IN FIRST-AID

"Among the remedies which it has pleased Almig God to give to man to relieve his sufferings none is universal and so efficacious as opium." Thus wr Sydenham in 1680, and his words are still true. It particularly in emergencies that its easy administra and relative safety make morphine invaluable; to injured man it not only brings relief from pain, and fatigue but may also be life-saving. It is th the main weapon in first-aid, whether this is give a doctor or by a regimental stretcher-bearer or na orderly in wartime. In peacetime only qualified do dentists, midwives, and the captains of ships are all to keep morphine for use in emergencies. How should this privilege be extended? This questio raised last week in a Manchester magistrate's c when Mr. Wilson Hey was prosecuted, at his own req in connexion with the supply of morphine to mou rescue parties and depots. For many years it been the policy of the Mountain Rescue Committe equip trained rescue parties with two rucksacks, containing first-aid necessaries, including two amp of gr. 1/3 of papaveretum, and the second "me comforts."[1] The rescue parties are fully instructed the use of these things and have attained a high stan of efficiency. The supply and replacement of their are centrally controlled, and Mr. Hey has hith personally supplied the morphine because the Ho Office would not sanction a direct supply, though applied for such sanction in 1934 and again rece To draw public attention to what he considered injustice Mr. Hey invited prosecution under the Dan ous Drugs Acts and was duly fined £10 and 10 gui costs. He pointed out that mine rescue parties, wh case seems closely analogous with the mountain are officially allowed to carry morphine. A still stro argument was that in the fifteen years during which has supplied the morphine, and has kept his committee record of all injections given, there have been no mish due to wrongful administration, and less than gr. 1⅓ unaccounted for. Nevertheless, as the law stands mountain rescue party can only carry and use morph on the rare occasions when it is accompanied by a doctor.

The aim of the dangerous drugs regulations is pres ably to prevent morphine falling into the hands of add and to prevent its being wrongly given to a casualty To an addict, gr. 1/3 of papaveretum will appeal more than a glass of mild ale to an alcoholic; and the careful records kept by Mr. Hey's committee seem to be a complete protection against misappropriation. The danger of the morphine being given without due ca must be small. In the war the crews of tanks and aircraft were equipped with syringe-ampoules which still further simplified administration, and the ma hundreds of injections that they gave to their inju comrades did much good and very little harm. The Mountain Rescue Committee has already been offici recognised by the Ministry of Fuel, who grant them petrol coupons, by the Ministry of Health, who gran them ambulance facilities and share in their work of maintaining rescue posts, and by the Ordnance Survey. Now that Mr. Hey has so bravely brought the subject to their notice, the Home Office might surely trust them with morphine.

Dr. DONALD HUNTER will deliver the Ernestine Henry lecture on Tuesday, Nov. 15, at 5 P.M., at the Royal College of Physicians of London. He is to speak on Devices for the Protection of the Worker Against Injury and Disease.

INTERNATIONAL TENSIONS
CHALLENGE TO THE SCIENCES OF MAN[*]

OTTO KLINEBERG
M.D., Ph.D.
ESSOR OF PSYCHOLOGY, COLUMBIA UNIVERSITY, NEW YORK

HERE is no need to repeat what has been said so often in so many different ways—that this is a critical od in our history. In previous generations there have . men who had reason to cry " These are the times try men's souls " ; but that brings us little comfort y. The combination of atom bombs, " iron curtains," nsive alliances, chauvinism, racialism, charges and nter-charges in the Cold War—all of this brings home s the reality of the danger. Everywhere in the world meets people who. because they feel helpless, are hopeless, and find a kind of escape in an apathetic gnation, doing nothing, just waiting for what may e.

his feeling of helplessness is perhaps the greatest ger of all. It paralyses action, even among those se action might count for something. It affects men gh places and in low. People everywhere are asking : hen will war come ? " ; not " Can we do anything to it from coming ? "

here are some important exceptions ; there are viduals and organisations that are doing what they Unesco is one such organisation. In the fields of ation, science, and culture, it is trying to cut across onal barriers and bring men closer together ; and of its important activities is its project on " tensions cting international understanding." This was coned by the general conference of Unesco at Mexico in 1947, and reaffirmed at Beirut in 1948, when the ctor-General was instructed to promote inquiries :

> The distinctive character of the various national cultures, ideals, and legal systems.
>
> The ideas which the people of one nation hold concerning their own and other nations.
>
> Modern methods developed in education, political science, philosophy, and psychology for changing mental attitudes, and the social and political circumstances that favour the employment of particular techniques.
>
> The influences which make for international understanding or for aggressive nationalism.
>
> Population problems affecting international understanding, including the cultural assimilation of immigrants.
>
> The influence of modern technology upon the attitudes and mutual relationships of peoples.

SOME QUESTIONS ANSWERED

et me begin by commenting briefly on some of the stions which we have been asked most frequently those who hear about the Tensions Project.

irst, what do we mean by " understanding " ? arly we do not have in mind simply an intellectual prehension, but rather understanding in its emotional affective sense : the kind of understanding that leads an attitude of friendliness. An " understanding " (in first sense) of the motivation and ideology of Nazism, example, would not necessarily involve " understanding " of the type with which the Tensions Project concerned. I shall return to the relation between se two varieties of understanding.

Secondly, what do we mean by " tensions " ? Psychologists are of course familiar with this term in the field of motivation, where it is often used as the equivalent of any unstable psychophysical state leading to action. In this sense tensions are normal, universal, inescapable. For present purposes, I would suggest that we are interested in tensions as states of strain, leading to action, commonly of an aggressive or hostile character.

Thirdly, tensions in whom, and where ? At one of the international meetings held by the Tensions Project, it was pointed out that this had never been fully clarified. The suggestion was made that at least three major varieties or levels of tension could be distinguished : (1) those within the individual ; (2) those within the group or nation : and (3) those between nations. It was urged further that if all of these—intra-individual, intranational, and international—tensions are important, we must show how they are interrelated and how they influence one another. Our major concern is naturally with the third group, international tensions : the others are, for present purposes, important only in so far as they affect these. As I shall try to show, these interrelationships are important and unmistakable, but their precise nature and extent require much more study before they can be completely appreciated.

Fourthly, we are asked whether we mean tensions in people generally, or in the leaders. " Wars begin in the minds of men," says the Unesco preamble ; but, whose minds ? What men ? The fact that most men clearly do not want war has sometimes led to the conclusion that the study of the minds of " most men " is irrelevant in this connexion. This conclusion appears to me unjustified. Granting that most men do not want war, they do want a number of things—security, national prestige, economic gain, a " way of life "—which they may believe they can obtain only through war. Believing this, they may think war evil yet also think it necessary. Leaders are important, of course, but they must have followers, and therefore followers are important too. The minds of leaders *and* of followers must equally be considered.

I shall turn now to an account of some of the activities which we have started, or are planning to start in the near future.

DIFFERENCES IN NATIONAL CULTURES

Pursuing the inquiry into differences in national cultures (or what has sometimes been called national character), we decided eighteen months ago to obtain comparable monographs on the " way of life " of different nations. These monographs are being written by persons of recognised competence, and before publication they must be approved by an editorial committee appointed by the International Studies Conference. They are not based on new empirical research, but bring together in a new synthesis facts and observations which are not always readily accessible. As a general description of national cultures, written by able representatives of such cultures, they constitute a valuable first step which should be useful for purposes of education, and also lead the way to more detailed research.

At a more intensive level, we have arranged for pilot community studies in France, India, Australia, and, probably, Sweden. In each country two small communities—one relatively industrialised, the other relatively rural—will be chosen, and to each community two investigators will be sent, one with his major training in sociology—ethnology, the other in psychology-psychiatry. Besides sociological description of the community, they will be expected also to bring back life-histories and Rorschachs, as well as other psychological protocols. The focus of the study will be on the problem of aggression, and its relation to various social and psychological factors.

---

[*] ased on a paper read before the section of psychiatry of the Royal Society of Medicine on Jan. 11, 1949, and on a presidential address to the Eastern Psychological Association at Springfield, Mass., on April 8.

Granting that legal systems are closely integrated with all other aspects of national life, and particularly with the political orientation of a people, problems in the field of comparative law should certainly not be neglected. A first volume of studies has been undertaken, with special reference to the difficulties which arise—between governments, between individuals and governments, and between individuals of different nationality—as the result of the differences in the legal systems of the "common law" countries and those deriving their legal practices and principles from Roman or "Continental" law.

There are many other possible approaches, of which I shall mention only three. First, the use of interview techniques, directed to a representative sample of the population in various countries, appears to have great promise. Granting the difficulties in international research of this type—and they have been amply demonstrated in international studies of public opinion—there are still some areas of interpersonal relationships which lend themselves to this approach. Some of the conclusions of Ruth Benedict regarding the Japanese, for example, or of Geoffrey Gorer regarding the Americans, could and should be tested on a representative sample of the nations concerned; also—and this is equally important—on other nations as well, so that we could determine to what extent the features ascribed to one national culture are peculiar to that culture. Secondly, it would be of great interest to collect and organise the experiences of psychiatrists and psychoanalysts who have practised in more than one country, or whose patients are of different national origin. Finally, the problem of "borrowing" among nations is an interesting one. The books and plays from the United States, for example, that are successful (or unsuccessful) in France and England respectively, may tell us something about the French and the English.

STEREOTYPES

Nations have conceptions or "stereotypes" regarding other nations as well as regarding themselves. To throw light on these an extensive investigation of the "public opinion survey" type was carried out in the United States, France, the United Kingdom, Australia, the Netherlands, Norway, Italy, China, and Mexico. Among the questions asked were:

> "From the list of words on this card, which seem to you to describe the American people (the Russian people, the British, French, Chinese, your own countrymen) best?
>
> Which people do you feel most friendly toward? Least friendly?
>
> Do you think that our (British, American, &c.) characteristics are mainly born in us, or are they due to the way we are brought up?"

Altogether there are 14 questions and they were asked of 1000 respondents in each country. The data are being analysed and prepared for publication by Henry Durant of the British Institute of Public Opinion.

Studies of the stereotypes of children and adolescents are being carried out in England, Switzerland, Belgium, and the Near East.

The controversy as to how stereotypes arise, and whether or not they always contain a "kernel of truth," has not entirely been settled. If—as I believe—some stereotypes do contain such a kernel and others do not, it seems to me highly important to bring home to people the exact nature of the relation between the stereotypes and objective reality. For this reason I see the first two inquiries of the Tensions Project as closely interconnected. On the one hand we need the objective facts regarding national cultures, and on the other the "subjective" facts as revealed in the stereotypes, and a comparison of these two sets of facts to determine the extent of agreement. Closely related to this are the problems of the degree of similarity in the stereo held regarding one nation by a number of other natio the changes in the nature of the stereotype through ti and the relation of such changes to specific econom and political alignments; the interaction betwe stereotypes and attitudes; and the extent to which th stereotypes are really believed.

WAYS OF CHANGING MENTAL ATTITUDES

Our third inquiry—into methods of changing attitud —is the practical core of our project, and also one of t aspects with which I, for one, am least satisfied. T literature in this area is enormous; it is filled wi interesting suggestions, but with little that we c use with confidence in the field of internation relations.

At a conference on the subject held a year ago th delegates expressed approval of the Textbook Proj of the Education Department of UNESCO, and of th attempts to eliminate from textbooks all mater conducive to international hostility; they urged furth the development of textbooks which will show how ev culture has borrowed much of its content from oth nations and other cultures, and the extent to which th whole of mankind is interdependent. We have arrang for the preparation of such a history textbook in th case of France, and when completed it will be sent t historians in other countries as a model for possible wo which they might like to do. But this attempt of ou unfortunately runs counter to a strong tendency ev denced in certain countries today who are claimi credit for all, or almost all, the contributions to ou civilisation.

Another resolution by the conference has to do wi contact as a factor in attitude change. It reads, in pa as follows:

> "The delegates express their support of UNESCO activiti relating to 'exchange of persons,' and urge the expans of the programme of fellowships, visiting professorship &c., as one means of replacing national stereotypes by mo objective experiences; at the same time they suggest th such a programme be combined with a scientific investi tion of the conditions under which 'exchange of persons favours international friendship, and the conditions unde which such contacts have the opposite effect."

We need help in broadening this type of study. In almo all countries there are international contacts of variou kinds and differing duration, through the travel of tourists, students, professors, merchants, diplomats, armies of occupation, &c. What are the effects on th travellers? On the people among whom they travel? In their own nation when they return? How do the effects differ according to the nature of the contact? Its duration? The age at which it occurs? The are only a few of the questions to which we nee answers.

Another suggestion reads:

> "There is need for an accurate and complete descripti of the major tensions and conflicts found in the world tod and of the variations in the nature and intensity of suc conflicts; this may be expressed in terms of a 'world ma and a 'world barometer' of tensions."

Here we felt it advisable to have a survey of the method which can be used for this purpose. We therefore wel- comed the news that the Society for the Psychological Study of Social Issues was planning a volume on The Measurement of Prejudice, and we made a small financial contribution to its preparation.

Another activity in this field which UNESCO is starting is an investigation on the relation between prejudice in teachers and prejudice in children. This study is being conducted by the New Education Fellowship, an international education organisation with headquarters in London.

epeat, we need help in this whole field. I would say we particularly need help as regards the relation een information and attitude change. Much of sco's work appears to proceed on the assumption knowledge about other nations increases friendship at cognitive or intellectual "understanding" means tive or emotional "understanding" as well. The resolution of the Tensions Project dealing with the ledge of national cultures, implies such a causal ionship. This is certainly not always true. When true? Under what conditions? Through the use of media? At what age? I know of no problem more rtant at this stage of our work, or with greater tical potentialities.

CAUSES OF TENSION

ır fourth inquiry deals with the "influences which e for international understanding or for aggressive onalism." Last year a meeting was held of social ltists coming from Brazil, France, Hungary, Norway, United Kingdom, and the United States. The eight ıl scientists present agreed on a general statement on e causes of tensions which make for war," and this ement has been widely distributed and widely ussed. Comments on it have ranged all the way the one extreme of believing that if only the world's ers would take it seriously there might be no more to the other extreme which looks on it as a series of ty platitudes. My own judgment is that it has some importance as an indication that at least on some c points social scientists from the two sides of the n curtain" (or Semi-permeable Membrane) can reach igreement, and that it could be useful as a basis for her coöperation in the future. We are now looking rard to the early appearance of a volume to which ı of these eight social scientists has contributed a pter and which will be published by the University llinois Press under the editorship of Hadley Cantril, ner director of the Tensions Project.

t the meeting of the general conference in Beirut at end of 1948, the Tensions Project received an ruction in the following terms:

> "A conference of experts should be convened to study ıd report on the techniques and devices used to bring bout Fascism in Italy and Germany in the period preceding ıe second world war in order to assist in the early recogni-on of such movements in the future. The results of this udy should receive wide publicity."

rk has already started along these lines.

n this whole area of "influences which make for inter-ional understanding or aggressive nationalism," it ns to me that we should bring together, and if possible end, investigations along two different lines. In the t place, we need to understand the way in which erent societies have, through their institutions, alised, directed, developed, or reduced aggressive aviour, as well as the outlets or substitutes for aggres-ı which they have invented. We would look especially he material available in ethnological monographs or he studies of individual communities by sociologists. the second place, we need to know how, within the ıe society and under relatively similar conditions, ıe individuals develop aggressive behaviour and others not. Here we need especially the help of psychologists l psychiatrists. A great deal of extremely valuable terial is available in both these directions. What is ticularly required is to have such materials more sely integrated. The relation between intra-individual l international tensions, to which I referred earlier, st be approached from both directions at once. ra-individual tensions do often lead to hostility against ıority groups and foreigners, but not always. Why? ernational tensions may be current in a community, but they do not equally affect all individuals. Why? The community studies which we are projecting may give us some insight into this problem, but it can only represent a first step. We need to know—and to do—much more.

POPULATION PROBLEMS

Plans have been developed for the publication of a volume, to be edited by Kingsley Davis of Columbia University, in which several social science disciplines will be represented. Among the chapters there will be one by the French demographer and jurist, Pierre Lambert, which shows the extent to which international tensions are determined, not so much by "actual" population pressure, but rather by "felt" population pressure, and indicates that the two are not always closely related; one by the Belgian sociologist, Pierre De Bie, on the effect of contacts between members of different national populations, somewhat along the lines described above; one by the American historian, Saul K. Padover, on the relation between the ethnic structure of populations and the existence of ethnic minorities, and international tensions; one by the English psychologist and psycho-analyst, J. C. Flugel, on population policies and ideologies. This will be a first survey of the field, but I think it will represent a real contribution. I may add that the Tensions Project is particularly interested in the problem which will be discussed by Padover—namely, the relation between intranational and international tensions—and we are hoping soon to begin a more intensive investigation.

A conference on population problems just held by the International Union for the Scientific Investigation of Population Problems dealt especially with the cultural assimilation of immigrants. Clearly the movements of populations, both voluntary and forced, have very real implications for international relations.

TECHNOLOGY AND MAN

The sixth inquiry is on "the influence of modern technology" on the relationships between peoples. So far we have done almost nothing in this field, but our plans are beginning to take shape.

Modern industrial and technological developments have taken from human beings almost all the satisfaction which formerly went with the accomplishment of a task; they have very largely substituted the reward of money for the reward that comes from the consciousness of work well done. It has been suggested that this denial of what the psychologists of a bygone day called "the instinct of workmanship" means widespread dissatisfaction, and with it a greater tendency toward aggressive behaviour. We may obtain some information along these lines from our community studies, since within each nation we shall have an industrialised and rural community for comparison. My own guess is that the problem of the effect of technology on tensions has often been over-simplified, and that the relation between satisfaction and achievement on the one hand, and aggression on the other, is exceedingly complex.

The programme of President Truman with regard to the economic development of so-called backward areas makes this problem a particularly urgent one.

OTHER UNDERTAKINGS

Some of the other activities of the Tensions Project may be mentioned briefly.

Gardner Murphy, in New York, is making a study of leadership, from which we hope to learn something about the way in which leaders in different countries have risen to important positions, and how some individuals get to be leaders who are later diagnosed as pathological.

David Katz, in Stockholm, is studying the various ways in which individuals are organised into groups having international connexions and implications, often without their being aware of it. This may serve as a first step in the investigation of the relation between national and international identifications and loyalties—a problem of the greatest importance in connexion with the possible future widening of such loyalties.

The Tensions Project is collaborating in a study of the technique of international conferences, and the difficulties and barriers encountered in such conferences.

Two very recent developments seem to me of special importance.

First, we are proposing to collect and publish a number of statements made by recognised scientific organisations in various parts of the world concerning race differences and racial prejudice. These statements, though made during the war in connexion with Nazi racial theories, still have very real pertinence and importance today. We then plan to call together a group of experts to examine these statements, as well as others that will have been collected for that purpose. These experts will be asked to formulate their own statement, either based on those already available or specifically constructed by them. The statement agreed upon by these scientists would then be submitted to Member Governments in the hope and expectation that it might represent a basis for an international declaration concerning race differences and race prejudice.

The Social Sciences Department of UNESCO thinks it of great importance to embark on an "educational offensive" in this area. The public generally believes that race differences are important; race prejudice is widespread. Scientists generally regard race as unimportant, and see no scientific justification for race prejudice. It will be the task of this educational offensive to reduce the gap between popular and scientific knowledge in this respect.

Secondly, the ministry of education of India has informed us of its plans to study tensions in India, and has asked for our coöperation. This is the first time that a Member State has asked the Tensions Project for help in the investigation of tensions within its boundaries. We shall be associated in the over-all planning and organisation of the work, and in the choice of specialists responsible for its integration, and we hope to be of some assistance to the Indian government in locating the major areas of incipient as well as of actual tension. More important, we hope eventually to make some suggestions of a practical nature.

TWO FINAL QUESTIONS

I started with a few questions which we have frequently been asked. There are two others which I have left to the last; they are the most obvious and perhaps also the most difficult to answer in a satisfactory manner.

The first is: what about the greatest tension of all, that between the United States and the U.S.S.R.? What are we doing about that? The U.S.S.R., unfortunately, is not a member of UNESCO, and we cannot bring American and Soviet social scientists together. On the other hand, it is still possible to bring together scientists from the two sides of the "curtain," since Hungary, Czechoslovakia, and Poland are Member States. Relations between "East" and "West" in UNESCO are cordial, and contacts are not only possible but frequent. This is obviously only a second best, but it is better than nothing. We have been thinking of having "neutral" nations make studies of the activities within the two Great Powers which contribute to the increase of tensions—for example, the part played by newspapers and other mass media. So far, I regret to say, we have not been able to carry through this plan, but we have hopes.

The second question is: what about the practical implications of all of this? Is the Tensions Project encouraging research or is it planning action? Our is, of course, research leading to action. There is a and obvious danger in action which is premature; t is an equal danger in delaying action until it is too lat and our major difficulty lies in steering the proper cou somewhere in between. We hope that when our work continued for some time, and when the results of many investigations which have been started can integrated, the practical implications may be m evident.

In one direction we already have a practical accompli ment to which we can point. We have succeeded, think, in bringing social scientists in different count a little closer together. We are at least partially reduc the distance between those countries in which so science is well developed and those in which it is s in its infancy. Nothing has been so sincerely hea warming to me in these few months in UNESCO as t eagerness shown by groups of social scientists and stude in so many places to learn what is happening elsewh and to join in a common undertaking. It is not exa "one world" in the social sciences as yet, but intellect communication is growing somewhat easier, and cont are gradually being established on an increasing sc An ever-widening circle of friends and colleagues working towards the same goal.

This circle must be made still wider. Those who stu man are called upon to help man. This is the challe which we face. In our own individual work, better s in collaboration with those trained in other disciplin and whenever possible with our colleagues in ot countries, we must devote at least some of our time, energy, and our techniques to the problems of int national relations. UNESCO has made a small beginni but it can do very little if it does not have the cooperat of social scientists everywhere.

Now my final question. Can social scientists make real contribution to the peace of the world? There ca be only one answer. Let us try.

INSTITUTE OF DISEASES OF THE CHEST

London's resources for postgraduate teaching ha been developed a stage further by the completion, in th grounds of Brompton Hospital, of new premises for t Institute of Diseases of the Chest. Last week the build was opened by Sir John Anderson, chairman of t British Postgraduate Medical Federation, to which t institute belongs. Teaching is conducted partly the staff of the Brompton and London Chest Hospita which are now administered as a single teaching unit Both have a long and important tradition of teachin and research, as Sir Robert Young and Dr. S. Roo house Gloyne were able to show in brief retrospects a last week's ceremony; but until lately, as Sir Franc Fraser remarked, these and other special hospitals i London have had less than their due place in teaching That this is now being rectified is due to the enterpri of the postgraduate federation, sustained by Londo University and the University Grants Committee.

Nearly half the new building is devoted to research laboratories, where functional and pathological investiga tions will be carried on side by side—an alignment not always achieved in the past. The teaching end of the building includes not only a lecture-room, library, and museum but also a large refectory; there is growing recognition that for postgraduates the value of such a room is not simply, or even primarily, social and nutri tional. Among the smaller attractions is a viewing-box constructed in the nearby hospital, with illumination from a single fluorescent tube, which is covered by frosted 'Perspex'; this gives remarkably uniform lighting.

N ZEALAND MEDICAL SCHEME AMENDED

FROM OUR NEW ZEALAND CORRESPONDENT

·tober, 1949, has seen the passing of two important ndment Acts relating to medicine under social rity. Both were hurried through in the last weeks ie session, and aroused little discussion. Members of iament have all eyes and ears on the general election e held at the end of November this year. On the ome of this there is little confident prediction. Labour Party have held power in this Parliament ı very thin margin, and their handling of the con-)tion issue, waterfront disputes, and other questions alienated some support.

THE MEDICAL PRACTITIONERS AMENDMENT ACT, 1949

he first of the two Acts deals with disciplinary ters in medical practice under social security. In eight years since general medical services were ın there has been no mechanism for dealing with rs and abuses. The new Act remedies this by stituting a Medical Practitioners' Disciplinary Com- tee and divisional disciplinary committees (of 6 nbers in the case of the four main centres, and 3 in ller centres). That the responsibility for discipline been entrusted to the medical profession is shown the facts that all members of all the committees are lical men, and in all cases are appointed by the ncil of the British Medical Association, except 1 nber of the 5 constituting the central committee,) is to be appointed by the minister of health.

he disciplinary committees are to deal with all rges against practitioners—anyone may make the rges—which fall short of grave impropriety or ımous conduct. In the latter case, the existing dical Council remains the appropriate body, and it is) now constituted a "higher court" to which appeals m the disciplinary committees go. Above the Medical ıncil remains, as at present, the Supreme Court. e disciplinary committee may fine up to £100, censure, order payment of costs of inquiry. The fines, queerly, to be paid to the B.M.A.: but this appears to be t of a plan to secure maintenance funds for the ıduct of these inquiries, though government responsi- ity for such funds is in part acknowledged. The nmittees are to regulate their own procedure subject any rules made by the Governor-General by Order in ıncil. The Medical Council remains much as before. may now fine up to £100 (formerly £50) and move the preme Court to remove a name from the register as fore.

These provisions are necessary and long overdue, and the whole have been fairly planned. How far they ll be able to cope with the admitted abuses of a ıeme which in some of its essential features is prone error, remains to be seen.

THE SOCIAL SECURITY AMENDMENT ACT, 1949

Part 1 of the second new Act deals with the rates of e following monetary benefits: superannuation, age, dows', orphans', invalids', sickness, unemployment, d miners'. In general these are all raised by about % from June 1, 1949.

Part 3 deals with medical services, and is to come into rce on a day to be appointed by the minister of health. he chief provisions are:

1. There is to be a prohibition of simultaneous practice ıder capitation and fee-for-service.

2. The refund system hitherto approved by the B.M.A. is t to apply unless specially authorised by the association ter consultation with the minister.

3. Power is taken to establish the specialist services under regulations with a recognised scale of fees and a list of recognised specialists, and provision for determining what constitutes a specialist service.

4. The right of medical practitioners to recover fees at law is restored. The disciplinary committees may be used as referees by the courts in such disputes.

It will thus be seen that some attempt has been made to implement the recommendations of the Joint Committee on Medical Services.[1] The major issue—specialist services—is left to regulations.

Medicine and the Law

Royal Cancer Hospital Reprieved

THE Court of Appeal has reversed the decision of Mr. Justice Harman respecting Mrs. Kellner's bequest to the Royal Cancer Hospital of one-eighth of the residue of her estate. The learned judge had ruled that the operation of the National Health Service Act, 1946, had brought to an end this charity which Mrs. Kellner had intended to benefit. Voicing some vigorous comments on the work of the Parliamentary draftsman, he held that the Act omitted to provide for the destination of such a legacy and that the gift must be deemed a valid charitable bequest and must be administered by the Crown under the Sign Manual.[2]

The Court of Appeal considers that the hospital, which was incorporated by royal charter in 1910, has not been dissolved by section 78 (1) (c) of the Act. That section enacted that "governing bodies of voluntary hospitals transferred to the Minister by virtue of this Act, whose functions wholly cease in consequence of this Act" should be dissolved as from July 5, 1948, when the Act was brought into force. This did not dissolve the Royal Cancer Hospital, but merely abolished its old committee of management. The draftsman, said the Master of the Rolls, had not been so negligent as the trial court had suggested. The case was precisely covered by section 60 (1) (a) of the Act whereby trustees can make payments "in the case of a hospital designated as a teaching hospital . . . to the Board of Governors of that teaching hospital." The Court of Appeal decided that Mrs. Kellner's executors must apply the appropriate fraction of her residuary estate for the purpose of making payments to the board of governors of the hospital in accordance with the terms of section 60.

Thus the Royal Cancer Hospital, over which Mr. Justice Harman had pronounced sentence of death, is reprieved. Section 77 (1) of the 1946 Act empowered the Minister to amend or repeal any charter which might appear to him inconsistent with the new Act or redundant in consequence of its operation. The Minister has not exercised that power; consequently the corporate body remains undissolved.

---

[2] See *Ibid*, 1949, i, 882.

". . . We know that poverty and hardship, danger and pain, are more favourable to character than riches, ease, safety and unfailing health: and, what is less well recognised, often more favourable to happiness too. Circumstances stick a pin into a human being, sometimes a very big one; then if his reaction is sound he is the better for the experience. Physical illness, financial catastrophe, national disaster, by such things as these men and women are probed. . . . Such men and women are strengthened and find happiness by the gallant exercise of faith and resolution in the face of great disappointment. They are "making good"; and that can be making good spirit in a real creative sense, with an effect on the balance of good and evil in circulation."—A SURGEON, at a Conference of Hospital Chaplains, 1949.

In England Now

A Running Commentary by Peripatetic Correspondents

SOME of the migratory movements of birds act as sensitive indicators of the weather, especially of the average temperature. One of these is the southward trend of the black-headed gulls in autumn to the Thames, where they stay till the next spring, when their disappearance to their breeding-sites is thought to be governed mainly by the effect of the increasing amount of daylight on their gonads. (These birds must not be confused with the black-backed gulls, which are always with us in London.) Last year the black-headed gulls had established themselves in strength along their beat between Westminster Bridge and Charing Cross by Oct. 1. This year, except for half a dozen forerunners, they did not arrive until Oct. 28, when at least forty were counted through the thick fog. Since these birds, unlike the immigrant starlings which possibly inform us of the weather in the Baltic area, come chiefly from other parts of the British Isles, their late arrival this year confirms the fact that the average temperature in our islands has been warmer than usual during the past month or so. It does this better than the amount of sunshine, which you show bears little relation to the incidence of poliomyelitis (p. 808), for the amount of sunshine obviously gets less and less as the "evenings draw in" and is no true indicator of the temperature.

* * *

Replete with horror stories and phenobarbitone, twelve of us presented ourselves at Upper Heyford for training as an R.A.F. Medical Parachute Rescue Team. An introductory talk informed us that when we had completed the course we would not be entitled to any parachute badge; that the six sisters and W.R.A.F.s, by virtue of their sex, would earn two-thirds of the jumping pay of the men; that everyone was very pleased to see us; and that the Army trainees had been briefed to pretend that it was entirely natural for girls to throw themselves out of aeroplanes and they needn't therefore expect to be stared at.

Four days were spent in training us for our first jump; days in which through constant repetition we learnt to react automatically to the words "Green on—GO." In these four days, dressed in our "suits combination drab," we were taught to land from ever-increasing heights; graduating via the swings, Leo's Leap, and the Fan to the eighty-foot Tower. The Fan is by far the worst piece of training apparatus. It consists of a series of small cubicles in the training hangar roof reached by climbing a vertical ladder 30 feet high. After clipping on a harness, one then tries to leap smartly out, seemingly on top of the upturned faces of one's waiting colleagues, the fall being broken by the harness wire unwinding from a drum against the resistance of a two-bladed fan.

Our first jump was graced by the presence of the B.B.C., complete with microphones and a reporter who went up in the cage with us. Having been told in the strictest confidence, at noon, that we were to jump at two, your correspondent spent an anorexic lunch watching the two sisters tucking in. The ascent in the balloon was rapid and we were kept well occupied by our dispatcher. The worst moment by far was when we stopped climbing and the balloon floated silent and stationary, 700 feet up. For the last time the dread phrase "Well, let's have you first, Doc" was heard. Standing in the door I was amused to see a very pale reporter watching me, and then I became distinctly annoyed at having placed myself in such an absurd position. Shortly afterwards I was amazed to find that four days' training had been sufficient to make me step into space and remain stiffly at attention. As I fell I watched a lorry going along a road beneath me rapidly increasing in size and was ashamed to feel the proverbial wave of fear pass up my body and exit as a groan. The canopy developed without any jerk and with a comforting thwack of nylon about three seconds after I had jumped. I spent the next twenty seconds having a good look round, listening to the instructor talking over the loud hailer, and blessing my parachute-packer. After the earth had come up and hit me I waited for the rest my stick to land before we all went off for a cup of N tea; a fluid which is usually considered somewhat but which on this occasion tasted like nectar.

One more balloon jump and several from aircr spread over the next few weeks completed our trainin There was a casualty-rate of two—one male refusal the second jump and a first-degree Pott's in a femin ankle on the last jump. The last two jumps were d with full kit. Everyone jumped with a chest p containing their personal kit, while the men, in additi jumped with all the medical stores in kitbags (weigh 50–60 lb.) strapped to their right leg. The tents, fo supplies, and other heavy stores were delivered in co tainers in a subsequent drop. After a few ground schem we found we could get a small tented hospital ready casualties within half an hour of the team leader jumpi from the aircraft.

The outstanding impression one gets of the train station is that everyone treats jumping as the m natural thing in the world, and the enthusiasm is s that all the station personnel from the command officer down to the smallest boy behind the officers' try to get in as many jumps as can be arranged. O instructors, with literally hundreds of jumps to th credit, were first regarded as demi-gods; but they rapid resolved into "Nobby" and "Jock"—two people wi infinite patience and an amazing capacity to anticipa and thereby dissipate our fears. We in our turn we able to render somewhat similar service, since they bo became fathers during our training time.

* * *

Your peripatetic correspondent, who *religiously* sca first "In England Now," and next the examinatio results to see who have outstripped him in the race fame and multiple diplomata, has been much impres by the high percentage of passes obtained by candida from overseas. On proceeding, however, to a statistic analysis, he finds that the percentage is not as high it seems at first sight. In the random sample: Mah rajah-di-Rajah Sri Bahadur Ram Singh Dhobiwalla Sahib, Ubanga N'Gonga Adenoma, Mohammed Abd Hassan Ali el-Gezira, and T. Brown, the percentage home-grown names is not, as might be supposed from cursory glance, 1%, but 25%. This finding leads o to reflect on the reasons for the relative as well absolute paucity of home-grown names, or autochthonou cognomina. Hitherto the practice of inserting Christia names in full has been reserved for the female in the islands, possibly in order to obtain an apparent increa at the expense of the male; but it might well be extended in the interests of national solidarity, to the male als J. Smith would then blossom as John Smith—a 50% increase. The alternative, to deprive foreign candidates of the right to have their names printed in full, is unthinkable. For one thing, nobody knows which is surname in the list; and for another the decline in prestige from Ilkla Moorbah Tat to I.M. Tat would be disastrous. Some candidates, however, have names which are æsthetically unsound whichever way one looks at them—e.g., O Tin Hat. These might well be excluded from the examination in the first place, and practical step would thus be taken towards the desired objective of increasing the possible percentage of humdrum or autochthonous cognomina aforesaid in the pass list, if only by decreasing the opposition. A few odd English names might have to be barred too, in the interests of fairness, but not, of course, *mine*.

* * *

We can't let our peripatetic colleague from the Persian Gulf get away with his of Oct. 22, can we?

It is hardly quite rait
To rhyme "late" with "Kuwait";
But here's the more serious fehling:
Sugar rations for two,
Wouldn't shift it from blwo,
Unless he were grievously ehling.

And surely in my day Fehling's solution turned from blue to yellow to brown, and it was Benedict's that turned red.

Letters to the Editor

THE DISTINCTION AWARDS

R.—I agree with much that has been said by the s of the merit awards scheme. The task of assessing merits of one's colleagues is as distasteful as it is ult, and when the various bodies representing the ssion accepted the scheme they were unaware of its iled implications. But if we neglected to inform elves of those at the time we must accept at least of the responsibility for the omission, and we cannot pe from the facts that the profession did agree oöperate, and that the task is beyond the unaided ers of the central committee.

y object in writing this letter is to suggest that e important aspects of the scheme have been over- ed by its critics and too little stressed by its defenders. new procedure should not be condemned until it been viewed against the background of the vast al changes in which for better or for worse we are all, y-nilly, involved, nor until the alternatives have more consideration than they have hitherto received. his is not the place, nor have I the qualifications, liscuss all the causes of our present social condition : it is obvious that they are extremely complex, that the current reorganisation of medicine in this ntry is the resultant not only of our existing political ntation but also of the course which the evolution of lical science has taken, of the consequences of two ld wars, and of the effects upon our national finances world-wide economic developments which were the ction to our own industrial revolution. These changes ear to be to a large extent irreversible, and it is ikely that the present structure of medical organisa- n will be substantially altered, whatever political party in power. The future of private consulting practice ncertain, but it seems probable that most consultants l in future be increasingly dependent upon the payments they receive for their hospital work. If this be ceded, consultants' salaries are not only of concern themselves but through their economic effects will foundly influence the development of medicine.

No-one seems to have suggested that all consultants uld be paid alike, irrespective of their personal alities and experience. The only question at issue how varying financial rewards should be allotted. e Government proposes to base the awards upon assessment of personal merit, and this fact in itself s important implications which may well extend yond medicine. A common complaint, often made th some justice, against current political trends is at they tend towards an egalitarianism which stifles itiative and depresses all to the level of the lowest. is surely of great significance, therefore, that the present overnment should have recognised that differences professional merit exist and that financial rewards ould correspond to them. It would indeed be rash if e medical profession did anything to undermine ch an important economic principle.

How, then, are the different financial rewards to be llotted ? The main alternatives proposed are three : l) by age and length of service : (2) by grading appointments instead of individuals : and (3) by some method f personal assessment.

(1) It is generally admitted that the first method does othing to encourage initiative and individuality. The ashionable study of geriatrics has provided no evidence n favour of gerontocracy. Moreover even this simple ormula leads to a pitfall which seems to have been verlooked. If either age or length of service is to be the ole determinant of salary it will be necessary to pay all onsultants in the service on the same basis whatever heir appointment. Thus the consultant at Much-Binding-in-the-Marsh hospital will be paid at the same rate for his hospital work as the teaching-hospital physician or surgeon if they are of the same age, and through sheer weight of numbers men of average ability will take the bulk of the highest awards. Is this in the interests of medicine, and is it what advocates of this method of determining payment really intend ?

(2) At first sight the grading of appointments instead of individuals looks seductively simple, but I doubt if those who propose this have thought out what it involves. How are hospital posts to be graded, and what criteria are to decide how many of the different grades of consultant are to exist at a teaching hospital, a non-teaching hospital, a special hospital, a mental hospital, a sanatorium, and so on ? The merits of hospitals are the products of the merits of their staffs : to grade such appointments, even if it could be done fairly, would only be an oblique and collective way of assessing the merits of the doctors concerned. But such an assessment, based on the present status of hospitals, would be inadequate to the needs of the health service. *In many areas it is desirable to raise the efficiency of the consultants.* This is not likely to happen if local hospital appointments are to be graded by their present status, but it would be equally undesirable to upgrade the posts above the level of their existing holders and before it is certain that they can be suitably filled. The Spens Committee's method not only offers an encouragement to the holders of these appointments to upgrade themselves by their own efforts, but also guarantees that if a good man accepts such a post he will carry his higher salary with him. This is particularly important in the case of whole-time appointments. The whole-timer has long suffered from financial handicaps in comparison with his part-time colleague, and even now these have not been entirely removed. Nevertheless in future, wherever he is in the health service, he will have a fair chance of receiving an equal reward for his achievements.

(3) The third choice—assessment by personal merit—is admittedly unpleasant and difficult, but there is no more prospect of an easy course for medicine than for the nation. I hope that consultants will carefully consider all the alternatives to the merit awards scheme and ask themselves whether any of them is practicable. If not, I believe it is better for our profession to try to make the scheme work than to adopt the supine attitude of non-coöperation advocated by its critics.

London, W. 1. W. RUSSELL BRAIN.

SIR.—I am informed that I erred in stating last week that the Awards Committee was chosen by the Minister of Health, and that in fact its members are nominees of medical bodies. I apologise for this mistake, but having done so, am fain to admit that the true facts as to the origin of the committee do not reconcile me to its purpose or its procedure.

London, W.1. F. M. R. WALSHE.

⁂ The committee was appointed by the Minister of Health and the Secretary of State for Scotland. Of its 14 members 11 were nominated by the Royal Colleges and Scottish Royal Corporations, 1 by the Medical Research Council, and 1 by the universities' committee of vice-chancellors and principals. The members are : Lord Moran, P.R.C.P. (chairman), Sir Horace Hamilton (vice-chairman), Mr. Zachary Cope, F.R.C.S., Prof. G. B. Fleming, P.R.F.P.S., Sir Gordon Gordon-Taylor, F.R.C.S., Mr. J. M. Graham, F.R.C.S.E., Sir David Henderson, F.R.C.P.E., Sir Edward Mellanby, F.R.C.P., F.R.S., Sir John Stopford, F.R.C.P., F.R.S., Sir Harry Platt, F.R.C.S., Prof. A. L. Robinson, F.R.C.O.G., Dr. J. H. Sheldon, F.R.C.P., Sir Lionel Whitby, F.R.C.P., and Mr. J. M. Wyatt, F.R.C.O.G.—ED. L.

SIR,—Professor Thomson's letter last week contains an interesting idea for dealing with the knotty problem of distinction awards; but the method suggested is by no means original. *This method of drawing names* out of a hat was practised extensively by assessing committees in many regions.

I suggest that the medical profession should pass away the quiet winter evenings by playing a new card game. Two packs of cards—one pack with names of doctors printed on it, the other cards bearing one of the many titles now in vogue—should be printed. Each pack is shuffled and placed in a hat. Cards are drawn and compared. The game is called "anomalies."

Birmingham. F. E. D. GRIFFITHS.

SIR,—*I note with interest that* Professor Thomson, in his letter last week, says: "An Englishman will accept misfortune in a lottery with good grace and good humour, but he will resent deliberate classification in a grade inferior to that of a colleague as an injustice." He makes this statement about the English in support of his suggestion that, except for a few superlative individuals whose claims to eminence are unimpeachable, the matter should be decided by a lottery.

It is not unnatural to wonder whether this point of view has any relevance to some of the results which emerged in the main grading, and which could be easiest explained by the operation of a lottery. If this could be so it seems a pity that those senior hospital medical officers who are now *languishing in bewilderment and* the distress of being made deliberately inferior to their colleagues, were not given this comforting explanation of their misfortune, so that those of them who are Englishmen could now begin to exercise their prerogative of behaving as such.

BIRMINGHAM REGIONAL S.H.M.O.

FACIAL PARALYSIS AND POLIOMYELITIS

SIR,—In his valuable report of Sept. 17, Dr. Stapleton concludes that "though there is a suggestion that the cases of facial palsy unaccompanied by other paralysis had a cause in common with the cases of poliomyelitis, this hypothesis is not, of course, proven."

During large-scale epidemics of poliomyelitis, instances of uncomplicated unilateral paralysis of the face are by no means rare. Epidemiological observations bearing out the relationship have been supported by laboratory confirmation. Thus Steigman and Sabin[1] refer to a 7-month-old infant whose only paralysis involved one side of the face. Poliomyelitis virus was isolated from her alimentary tract, and antibody to the homologous strain of virus appeared in convalescence.

Facial "paralysis" is perhaps a better term than the time-honoured facial "palsy," at least for those cases where clinical and epidemiological evidence suggests *poliomyelitis virus as the cause.*

New York. ALEX J. STEIGMAN.

VENTRICULAR FIBRILLATION

SIR,—Dr. Robertson (Oct. 29) doubts the presence of ventricular fibrillation in the electrocardiogram recorded in my case-report (Oct. 15) because of the "absolute regularity of the aberrant complexes." I can assure him that my diagnosis was based on the very fact that the complexes are *not absolutely regular and show* definite variations in form and amplitude from beat to beat in those phases of the record referred to in the *report as fibrillation.* These variations can quite easily be seen in the published reproduction of the E.C.G., but I admit they are clearer in the original record which is not now in my possession; I believe that Dr. Robertson would have been convinced had he seen this.

Leamington Spa. W. M. PRIEST.

MANTOUX-CONVERSION

SIR,—*There is a place in the English* language f term to indicate a change from the tuberculin-ne state to the tuberculin-positive state, but the use two different terms with this meaning leads to co In the American and English literature the term " toux-conversion" is used to indicate this change, some Scandinavian writers have preferred the "Mantoux-inversion" and recently one English has followed them.[1] To the ordinary English re "conversion" clearly indicates a change from a *state to a* newly acquired one, while "reversion equally clearly indicates a change from an acqu state to a pre-existing one. "Inversion" suggests mer a "turning upside down," with no implication as the *nature of the change.*

For the sake of clarity and uniformity, therefore would be preferable for all writers on tuberculosis to "Mantoux-conversion" to indicate the change from tuberculin-negative to the tuberculin-positive state, shown by the Mantoux technique; Mantoux-rever is the correct term to indicate the change from tubercu positive to tuberculin-negative. I am sure that Scandinavian friends, who have such a remarkable enviable command of our *language, will be* willing drop the term "Mantoux-inversion," which has no etymological justification for use in the sense it acquired.

CHARLES NEWMAN
Chairman, Prophit Tuberculosis Survey Committee,
Royal College of Physicians.

THE M.O.H.

SIR,—Both Dr. Brockington *and* Dr. H. C. Mau Williams speak despondently about the future of pu health (Oct. 22, pp. 759 and 755), and yet in indust health is a great region of *public* health which is alm untouched. The problem is the environmental hygie of the small factory. Most people are employed in sm factories, many of which have deplorable standards, a the medical inspectorate, good though it is, is spread to thinly *to* produce much improvement. Why not medical supply match industrial demand *and* use th only sizeable body of men trained in preventive medici to raise the level of industrial hygiene? This woul provide an industrial health service where it is mo needed, at little extra cost in money or medical man power.

Medical School, King's College,
Newcastle-on-Tyne, 1. R. C. BROWNE.

VASCULAR STASIS

SIR,—In his letter of Oct 22, Dr. Shubsachs impli that my use of the term "whole-skin loss" in burn synonymous with blister formation. In so doing h *misunderstands* what is meant by the term "whol skin loss." This means more than mere epiderm destruction: it means that death of the epithelial el ments (follicles, glands, and ducts) has occurred throu out the whole depth of the dermis and that regeneratio of epithelium can only take place from the epidermis surrounding the burn.

In my letter of Oct. 15, I attempted to draw attention to the fact that stasis of the dermal blood-flow may *occur in burns, and that if it* develops through the depth of the dermis it is followed by necrosis of the dermal epithelium. In such a burn epithelial regeneration *from the dermis is impossible*—in other words, whole-skin loss has developed.

From Dr. Shubsachs's own description of the blister burns which he has treated with anti-histamine drugs, in which rapid epithelial regeneration from the dermis s, it is clear that only the superficial elements of the (epidermis and possibly the most superficial portion e dermis) had suffered irreversible heat changes. ich burns epithelial regeneration from the underdermis *normally* takes place fairly rapidly, and the d area is re-covered with epithelium in 7 to 14 days. e is no reason to assume that the anti-histamine s had any effect whatsoever. Such burns correspond puytren's grade 2, and in this unit would be called ficial partial skin-loss burns.

President Ligue Europeen.
OSWALD SAVAGE
Secretary, British branch of the Ligue
Internationale contre le Rhumatisme.

ACUTE MASTITIS

R.—Mr. Walsh (Oct. 8) refers to the responsibility he general practitioner in the early diagnosis and ment of acute mastitis, and in discussing the logy he mentions cracked nipple as an important r; but leaves one in doubt as to what exactly cluded under this head. Suckling is, or should be, inless process. In cases where the nipple is sore, roscopic cracks may be observed, but one cannot ys find them. That the sore nipple, without obvious ks, belongs to the same class as the cracked nipple ggested by the fact that both respond rapidly to cillin ointment applied to the nipple after each feed.

r. Hogg's letter (Oct. 22) about veterinary experience very interesting. I have never attempted to admini- penicillin directly into the mammary ducts, and problem obviously varies from one species to another. dersheim, in his *Comparative Anatomy of Vertebrates* 7, p. 28), gives illustrations to show the lactiferous ts of carnivora and ungulates opening into the bottom teat canal (it is into this that Mr. Hogg has injected icillin), while in primates, rodents, and marsupials lactiferous ducts open into the apex of the nipple there is no teat canal. Mr. Hogg's concluding rvation, that "the wise farmer nowadays has his icillin ointment always handy for immediate application at the merest suspicion of an abrasion, crack, or sore in the region of the teat orifice," is in strange contrast to the fact that midwives are not issued with penicillin ointment for use in the human subject.

Oulton Broad, Lowestoft. N. B. EASTWOOD.

MEASLES IN LONDON

SIR,—Dr. Breen and Mr. Benjamin, in their article of Oct. 1, maintain that since 1940 "the biennial epidemic rhythm [of measles in London] has disappeared." This might be true without invalidating the general truth as to the persistence of this feature when units of population far transcending that even of London are observed. The discovery of a type may be difficult: it may be a tardy induction based on a group of hitherto unrelated facts or quickly seen in an accidental illuminating flash of vision. But, once established as a more or less permanent feature of distributed phenomena or of recurring events, it is usually easy to recognise. A type may disappear, be transformed in its features, or survive so changed as scarcely to preserve its identity. Dr. Breen and Mr. Benjamin conclude that in London, since 1940, biennial rhythm, in any form hitherto recognised, can no longer be observed.

Controversy during many years has been as to its nature and description rather than as to the fact of the occurrence of biennial rhythm. Its disappearance with the advent of notification of measles in a population so large as that of London would be a noteworthy event. But the evidence on which the conclusion is based, as set out in the paper, is far from convincing: and it is not a little remarkable that it was upon the data from 1940 to the end of 1945, relating severally to London, to London and the great towns, to other towns and areas, and to England and Wales as a whole, that I formulated the thesis of the recurring multiphasic character of biennial incidence in measles.[1] The authors say that "a series of alternate heavy and light years, one year being mainly covered by an epidemic and the next year being mainly interepidemic" is to be observed both in London and New York. This description may be a facile way of distinguishing biennial epidemicity, but, exclusively so used, is little likely to disclose the natural course of measles epidemics. So to describe it is to ignore all but the gross annual numbers or recognise only the high peaks as evidence of epidemics. As I observed nearly three years ago[2]:

> "In the graphs of incidence of recent years there is seen to be comprised within a single span of four-and-twenty months the proportioned phases not alone of epidemic prevalence but also of the low levels of intercurrent sub-epidemicity. Thus seen, periodicity ceases to be a biennial recurrence of punctual maxima and becomes a periodic repetition of like prevalences each in its due season, once within two years."

Serial distribution of cases as they occur shows types of biennial periodicity not properly to be described as recurrences of epidemics in alternate years. And the main conclusion of the authors—that in London since 1940 the biennial epidemic rhythm of measles has disappeared at least temporarily—is not borne out by a detailed survey of the ten years 1940–49. The epidemics of 1940–41, 1942–43, and 1944–45 as shown in the graphs exhibit a biennial periodicity more comprehensive than that of biennially recurring peaks—though these also are to be observed: and while since then what might be regarded as fundamental changes have been noted, these are not coincident with the notification period. As Taylor[3] has demonstrated, measles outbreaks in lesser constituent populations may not conform to the type of incidence observable in the larger inclusive units such as England and Wales.

3. Taylor, I. *Mon. Bull. Min. Hlth, P.H.L.S.* 1948, 7, 254.

SIR,—Professor Thomson's letter last week contains an interesting idea for dealing with the knotty problem of distinction awards; but the method suggested is by no means original. This method of drawing names out of a hat was practised extensively by assessing committees in many regions.

I suggest that the medical profession should pass away the quiet winter evenings by playing a new card game. Two packs of cards—one pack with names of doctors printed on it, the other cards bearing one of the many titles now in vogue—should be printed. Each pack is shuffled and placed in a hat. Cards are drawn and compared. The game is called "anomalies."

Birmingham. F. E. D. GRIFFITHS.

SIR,—I note with interest that Professor Thomson, in his letter last week, says: "An Englishman will accept misfortune in a lottery with good grace and good humour, but he will resent deliberate classification in a grade inferior to that of a colleague as an injustice." He makes this statement about the English in support of his suggestion that, except for a few superlative individuals whose claims to eminence are unimpeachable, the matter should be decided by a lottery.

It is not unnatural to wonder whether this point of view has any relevance to some of the results which emerged in the main grading, and which could be easiest explained by the operation of a lottery. If this could be so it seems a pity that those senior hospital medical officers who are now languishing in bewilderment and the distress of being made deliberately inferior to their colleagues, were not given this comforting explanation of their misfortune, so that those of them who are Englishmen could now begin to exercise their prerogative of behaving as such.

BIRMINGHAM REGIONAL S.H.M.O.

FACIAL PARALYSIS AND POLIOMYELITIS

SIR,—In his valuable report of Sept. 17, Dr. Stapleton concludes that "though there is a suggestion that the cases of facial palsy unaccompanied by other paralysis had a cause in common with the cases of poliomyelitis, this hypothesis is not, of course, proven."

During large-scale epidemics of poliomyelitis, instances of uncomplicated unilateral paralysis of the face are by no means rare. Epidemiological observations bearing out the relationship have been supported by laboratory confirmation. Thus Steigman and Sabin[1] refer to a 7-month-old infant whose only paralysis involved one side of the face. Poliomyelitis virus was isolated from her alimentary tract, and antibody to the homologous strain of virus appeared in convalescence.

Facial "paralysis" is perhaps a better term than the time-honoured facial "palsy," at least for those cases where clinical and epidemiological evidence suggests *poliomyelitis* virus as the cause.

New York. ALEX J. STEIGMAN.

VENTRICULAR FIBRILLATION

SIR,—Dr. Robertson (Oct. 29) doubts the presence of ventricular fibrillation in the electrocardiogram recorded in my case-report (Oct. 15) because of the "absolute regularity of the aberrant complexes." I can assure him that my diagnosis was based on the very fact that the complexes are *not absolutely* regular and show definite variations in form and amplitude from beat to beat in those phases of the record referred to in the report as fibrillation. These variations can quite easily be seen in the published reproduction of the E.C.G., but I admit they are clearer in the original record which is not now in my possession; I believe that Dr. Robertson would have been convinced had he seen this.

MANTOUX-CONVERSION

SIR,—There is a place in the English language term to indicate a change from the tuberculin-ne state to the tuberculin-positive state, but the two different terms with this meaning leads to confu In the American and English literature the term " toux-conversion" is used to indicate this change, some Scandinavian writers have preferred the "Mantoux-inversion" and recently one English w has followed them.[1] To the ordinary English rea "conversion" clearly indicates a change from a state *to* a newly acquired one, while "reversio equally clearly indicates a change from an acqui state to a pre-existing one. "Inversion" suggests me a "turning upside down," with no implication the nature of the change.

For the sake of clarity and uniformity, therefo would be preferable for all writers on tuberculosis to "Mantoux-conversion" to indicate the change from tuberculin-negative to the tuberculin-positive state, shown by the Mantoux technique; Mantoux-rever is the correct term to indicate the change from tuberc positive to tuberculin-negative. I am sure that Scandinavian friends, who have such a remarkable enviable command of our language, will be willing drop the term "Mantoux-inversion," which has no etymological justification for use in the sense it acquired.

Newcastle-on-Tyne, 1. R. C. BROWN

VASCULAR STASIS

SIR,—In his letter of Oct 22, Dr. Shubsachs implie that my use of the term "whole-skin loss" in burns synonymous with blister formation. In so doing misunderstands what is meant by the term "whol skin loss." This means more than mere epiderm destruction: it means that death of the epithelial el ments (follicles, glands, and ducts) has occurred throug out the whole depth of the dermis and that regeneratio of epithelium can only take place from the epidermi surrounding the burn.

In my letter of Oct. 15, I attempted to draw attention to the fact that stasis of the dermal blood-flow may occur in burns, and that if it develops through the depth of the dermis it is followed by necrosis of the dermal epithelium. In such a burn epithelial regeneration from the dermis is impossible—in other words, whole skin loss has developed.

From Dr. Shubsachs's own description of the blister burns which he has treated with anti-histamine drugs in which rapid epithelial regeneration from the dermis

MEASLES IN LONDON

SIR,—Dr. Breen and Mr. Benjamin, in their article of Oct. 1, maintain that since 1940 "the biennial epidemic rhythm [of measles in London] has disappeared." This might be true without invalidating the general truth as to the persistence of this feature when units of population far transcending that even of London are observed. The discovery of a type may be difficult: it may be a tardy induction based on a group of hitherto unrelated facts or quickly seen in an accidental illuminating flash of vision. But, once established as a more or less permanent feature of distributed phenomena or of recurring events, it is usually easy to recognise. A type may disappear, be transformed in its features, or survive so changed as scarcely to preserve its identity. Dr. Breen and Mr. Benjamin conclude that in London, since 1940, biennial rhythm, in any form hitherto recognised, can no longer be observed.

Controversy during many years has been as to its nature and description rather than as to the fact of the occurrence of biennial rhythm. Its disappearance with the advent of notification of measles in a population so large as that of London would be a noteworthy event. But the evidence on which the conclusion is based, as set out in the paper, is far from convincing; and it is not a little remarkable that it was upon the data from 1940 to the end of 1945, relating severally to London, to London and the great towns, to other towns and areas, and to England and Wales as a whole, that I formulated the thesis of the recurring multiphasic character of biennial incidence in measles.[1] The authors say that "a series of alternate heavy and light years, one year being mainly covered by an epidemic and the next year being mainly interepidemic" is to be observed both in London and New York. This description may be a facile way of distinguishing biennial epidemicity, but, exclusively so used, is little likely to disclose the natural course of measles epidemics. So to describe it is to ignore all but the gross annual numbers or recognise only the high peaks as evidence of epidemics. As I observed nearly three years ago[2]:

> "In the graphs of incidence of recent years there is seen to be comprised within a single span of four-and-twenty months the proportioned phases not alone of epidemic prevalence but also of the low levels of intercurrent sub-epidemicity. Thus seen, periodicity ceases to be a biennial recurrence of punctual maxima and becomes a periodic repetition of like prevalences each in its due season, once within two years."

Serial distribution of cases as they occur shows types of biennial periodicity not properly to be described as recurrences of epidemics in alternate years. And the main conclusion of the authors—that in London since 1940 the biennial epidemic rhythm of measles has disappeared at least temporarily—is not borne out by a detailed survey of the ten years 1940–49. The epidemics of 1940–41, 1942–43, and 1944–45 as shown in the graphs exhibit a biennial periodicity more comprehensive than that of biennially recurring peaks—though these also are to be observed: and while since then what might be regarded as fundamental changes have been noted, these are not coincident with the notification period. As Taylor[3] has demonstrated, measles outbreaks in lesser constituent populations may not conform to the type of incidence observable in the larger inclusive units such as England and Wales.

1. Butler, W. *Mon. Bull. Min. Hlth, P.H.L.S.* 1946, 5, 81.
2. Butler, W. *Proc. R. Soc. Med.* 1947, 40, 384.
3. Taylor, I. *Mon. Bull. Min. Hlth, P.H.L.S.* 1948, 7, 254.

Taylor further noted that in London in the epidemic of 1946–47 there was a transposition of what customarily would have been the successive minor and major phases. This, together with the epidemic of 1948–49 just terminated (or terminating), may lend some support to the view that at least transiently annual rather than biennial epidemicity has become a feature of London measles. It was anticipated that "the minor phases as such may cease and, if enlarged and separated by definite sub-epidemicity from what follows, be regarded justly as completed epidemics. In that case, of course, biennial periodicity disappears and is replaced by annual recurrences."[2] The two—or, so regarded, four—most recent epidemics in London (1946–47 and 1948–49) may be instanced as illustrative of this anticipation, but it must not be overlooked that anomalies of incidence in London are to be expected.

The exodus of children at the beginning of the war could not fail profoundly to modify the course of measles prevalence in the metropolis. That for 1940–41, for instance, was diminutive; nevertheless, in attenuated form the features dominantly defined in composite graphs of the three epidemics of 1940–41, 1942–43, and 1944–45 are clearly to be traced ab origine. The epidemics of 1946–47 and 1948–49, while retaining anomalously, if regarded as biennial epidemics, the features of such, would if they were characteristically recurrent over a prolonged period be seen, I think, as annual epidemic recurrences. Extensively, during the period of evacuation, children who normally would have contracted measles in London escaped, and with their return have added to the numbers of susceptibles in the metropolis. This change in the immunity constitution of the population, the raising of the fee for notification which has made it worth while for the practitioner to seek out family contact sufferers from the disease, and other circumstances, contribute to such anomalies as those we are now witnessing.

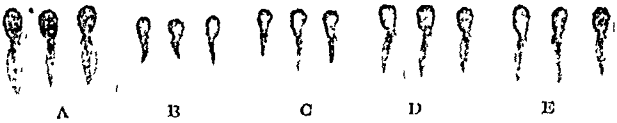
Ministry of Health,
London, S.W.1.

WILLIAM BUTLER.

ÆTIOLOGY OF GRAVES'S DISEASE

SIR,—In his most lucid and stimulating lecture, published in your issue of Sept. 24, Professor Means asks "How actually does thyroid hormone act on cells, and what potentiates or inhibits such action?" and he continues: "To these questions we badly need answers."

The problem of how the action of the thyroid hormone and of other hormones may be modified once they have been released by the glands, was studied many years ago by H. Zondek and myself.[4] The results of these old experiments are, I believe, interesting enough to be briefly recalled.



Tadpoles on 4th day of experiment: A, controls; B, thyroid action at pH 6·5; C, thyroid action on addition of 66 mg. calcium chloride per 100 ml. water; D, thyroid action on addition of 200 mg. calcium chloride per 100 ml. water; E, thyroid action at pH 7·4.

Using the metamorphosis of tadpoles as a test for thyroid hormone, we found that comparatively slight changes of the pH of the water in which the tadpoles were kept modifies thyroid action. Metamorphosis took place much more rapidly at a pH of 6·5–7 and of 7·7–8·5, than at a pH of 7–8 and below 6·5; and we concluded that the changes in hydrogen-ion concentration, as they occur in the body and between blood and tissues, may perhaps cause variation in hormonal response. Previously, Zondek and Reiter[5] had obs addition of small quantities of potassium and calcium enhanced and inhibited, respectively, the influence of hormone on the metamorphosis of tadpoles. The figure, taken from our own experiments, illustrates the act thyroid hormone on the metamorphosis of tadpoles calcium chloride is added to the water and when this is t at a pH of 6·5 and 7·4.

Similar observations were made with respect to hormones. Zondek and I[6] found that addition of quantities of calcium chloride to insulin diminished and times even reversed the action of insulin on the blood sugar. McCarrison[7] described modification of the action adrenaline by alteration of the pH, and Kylin[8] observ similar changes on addition of potassium and calcium salts.

Thus it appeared that variations in the concentrati of hydrogen ions and of certain electrolytes mi modify hormonal action.

London, W.1.

H. UCKO.

INTRAVENOUS IRON IN RHEUMATOID ARTHRITIS

SIR,—I was interested to read the results reported Dr. Sinclair and Dr. Duthie in your issue of Oct. 8.

Early this year I gave several patients with long-stan ing active rheumatoid arthritis a course of intraven iron ('Ferrivenin,' Benger). The general régime much the same as that of Sinclair and Duthie.

So far I have detailed results in only 3 cases. Ea of these patients had been under observation for at le a year, during which they had been taking iron regula by mouth. In no case was the anæmia very pronounc and the intravenous iron was given in the hope th apart from raising the hæmoglobin level to normal, would produce more general improvement which co be measured by means of the erythrocyte-sedimentat rate (E.S.R.). Hæmoglobin was estimated by Haldane method; and the E.S.R. at the end of one h by the Westergren method.

CONTROL OF TUBERCULOSIS

t,—I doubt whether, under the existing circum- es, many chest physicians will feel able to accede r. Temple Clive's request, in his letter of Oct. 22, their patients should be admitted to sanatoria conditioned" by bed rest only.

ny patients have to wait up to six or nine months e being admitted to a sanatorium, and during this d *not a few progressively deteriorate despite* bed which in many cases cannot be properly applied e patient's own home. Does Dr. Temple Clive usly suggest that these cases should not receive benefit of collapse therapy or of treatment with tomycin or para-aminosalicylic acid when they are he earliest, and therefore most treatable, stage? Temple Clive states that the results of domiciliary pse therapy have not been *uniformly* successful, collapse therapy instituted in a sanatorium is also ccessful in many instances; success in this field nds more on selection of the right type of case on whether treatment is instituted in the home or sanatorium.

long as there are not sufficient sanatorium beds the treatment of the tuberculous it is up to the t physician to treat his patients as best he can as as he can, and to this end the use of domiciliary pse therapy appears to be entirely justified. More- t, the suggestion that it is dangerous for the chest sician to treat his cases in the patients' homes, ther by collapse therapy or with streptomycin or a-aminosalicylic acid, is unfair to the ability of the st physician, who is quite as able to assess his patients to plan their treatment as is the sanatorium physician.

odsham, Cheshire. M. B. Paul.

IR,—In his letter of Oct. 22, Dr. Temple Clive warns that domiciliary collapse treatment in pulmonary erculosis should not be undertaken lightly. I should to support his warning most strongly.

omiciliary collapse treatment, like any other treat- nt, can only give good results in experienced hands l if all the necessary facilities are available. In my nion this treatment should only be undertaken if the owing conditions obtain: (1) careful selection of es; (2) adequate provision for the care of the patients home, including home help if necessary; (3) a chest ysician constantly on call to deal with emergencies; adequate facilities for adhesion-section and for renic crushes; and (5) a reliable transport system convey patients from their homes to the clinic for ills and X-ray control, and, if necessary, to institutions minor surgery.

I think, however, that domiciliary collapse treatment s come to stay, until the time when it will again be ssible to admit tuberculous patients to hospital without uch delay.

Since 1945 I have induced in the Hounslow chest- inic area nearly 300 pneumoperitoneums and artificial neumothoraces in the patients' homes. A preliminary port on the first 200 cases has lately been published,[1] and I think that the results certainly bear comparison with the results of institutional treatment.

I should like to plead for the more frequent use of the pneumoperitoneum as a preliminary collapse measure, especially as this will give satisfactory results even in less experienced hands and where there are less facilities for minor surgery and frequent X-ray control.

Hounslow, Middlesex.

R. Heller
Chest Physician.

NIPPLE-SHIELDS

Sir,—Your correspondents who advocate the use of lead nipple-shields are, unhappily, following in the footsteps of those who have from time to time made thorny the path of preventive medicine.

The first principle in the control of poisoning by specific agents is replacement of the toxic material by one that is harmless, and the arguments adduced in favour of lead shields have a familiar ring to those who recall the struggle of the last half-century to reduce the toll of industrial disease. One of the reasons for the great reduction in the incidence of lead-poisoning among industrial workers since 1900 has been the successful adoption of this principle. At one time lead was an essential ingredient of glazes, and the pottery industry was notorious for its lead-poisoning. Now, leadless glazes have been found to be so successful that their use has been prescribed by law. This is but one example of many that could be mentioned.

The use of lead in occupations is so fraught with risks to health that it is hedged around by innumerable restrictions, yet it is seriously suggested that this most dangerous of metals is a safe substance to interpose between an infant and the breast. Exhortations to cleanliness and restricted use are futile, for there is no-one to see that these instructions are carried out.

I would draw the attention of your correspondents to the late Sir Thomas Legge's second axiom for control of industrial disease. He said: "If you can bring an influence to bear external to the workman (i.e., one over which he can exercise no control) you will be successful: if you cannot, or do not, you will never be wholly successful." For workman read nursing mother, and the rule holds good.

Usher Institute,

Catherine Swanston
Lecturer in Industrial Health.

Sir,—Whether or not lead shields can induce healing of a damaged nipple, it seems clear that their use must be given up. I have always thought that any good they did was more likely to be by keeping the injured surface from contact with clothing than from a deposit of lead salts. If so, a shield made of glass or some safe type of plastic material should do equally well and avoid risk to the child.

The very great majority of these injuries will heal quickly—in 24–48 hours rather than the week implied by Dr. Gordon last week—if, from the first experience of pain, suckling is withheld, the milk removed by hand, and the nipple surface protected. This has been the practice at this hospital for many years and has proved most satisfactory. The risk of mastitis is almost wholly saved and the woman spared suffering with its inhibitory action on the milk's outflow. When resumption of feeding reproduces the damage it is almost always because the nipple cannot be drawn by the baby far enough into its mouth. The likelihood of this should have been foreseen in pregnancy and a shield worn to improve its range of protraction.

May I support Mr. Nockolds and Dr. Moragas (Oct. 29) on the advantages of treating breast abscesses by aspiration—with one reservation? I doubt if a child should be allowed to feed at a breast which is acutely infected with *Staphylococcus aureus*. In pre-penicillin days I have known one infant die of enteritis from

---

1. Heller, R. *Tubercle*, 1949 30 204.

ingesting this organism, and another who developed staphylococcal pneumonia and fatal pyopericarditis. The risk must be much lessened once a high concentration of penicillin is achieved; but only then, and only if it is maintained, can I agree that suckling should be allowed. Gentle removal of the milk by hand avoids the risk, and I believe results in better drainage.

British Hospital for Mothers and Babies, London, S.E.18.
HAROLD WALLER.

AEROSOLS BY INHALATION

SIR,—I was very surprised not to find in your leading article of Oct. 8 any reference to the 'Aerohaler' method of delivering micropulverised substances to the respiratory mucosa; especially as you say:

> "... *the need is for a simple apparatus with an accessible nebulising device which can be quickly cleaned.* ... *It should then be possible to abort the annual attack of recurrent bronchitis, to control the acute phases of bronchiectatic inflammation.* ..."

The manufacturers of the aerohaler claim that this means of delivery permits a more even and wider distribution of the material, together with a greater concentration per unit area. Its simplicity is unquestionable, and its effectiveness is also beyond doubt; for confirmation one has only to consult the report on 357 cases of various respiratory infections treated by Krasno, Karp, and Rhoads,[1] or to question other medical men who have used it. I have myself reported on a large lung abscess dramatically cured by this method.[2]

Galway.
D. T. O'DRISCOLL.

THE DOCTOR'S CREED

SIR,—I suppose that if the Archbishop of Canterbury enters the pages of a scientific journal [3] it will be his wish to do so on equal terms with others, and that, since he draws upon argument rather than authority to make his case, he will not mind some of his premises being called *into question.*

I speak as one who has given a good deal of thought to the ethical questions raised by being a doctor and a teacher, and indeed by life itself, and this seems to be an ideal opportunity to raise what to me, with some training in scientific reasoning, is a fundamental objection to the acceptance of the doctrine, though not the ethic, of orthodox Christianity.

It is quite impossible for me to believe that God is at the same time omniscient, omnipotent, and wholly benevolent. I have seen too many children die of leukæmia or nephritis to believe that "Man is the object of God's love, as God has shown in His acts"; and if, as Dr. Fisher asserts, God understands radar, then He surely knew of Buchenwald and Auschwitz. In short it seems that we must either believe that He is powerless to intervene against the evils of Satan and of man or that they are of His own creation. This, I am well aware, is no new objection; but just because it must be the stumbling-block of many thinking persons on the threshold of religion, so does it stand in need of an answer. Here let me anticipate the orthodox replies. To say that these are matters of Faith which we do not understand is to beg the question and renounce even the semblance of a logical approach to it. It is as if I were to say to my students "you must not question why you are to use this remedy or that; it must be enough that I who am learned in these matters say that you should do so." To say that because I have within me an instinctive knowledge of right and wrong it must have been given to me by God is to assert what I have not contested. And to say that Buchenwald had some divine purpose incomprehensible to man is to deny completely man's right to distinguish Good and Evil.

As if a little unsure that his beliefs will be acceptable, Dr. Fisher throws out the challenge man should accept them unless he has "a better thesis which will better equip him for his life and work." As there are today many earnest doctors, I hope beloved physicians, who do not subscribe to orthodox religious belief, I would try to state th as briefly as possible. They believe that as civilised educated men our conduct should be determined sense of personal responsibility; by the inner satis of doing right; because not to do so brings a personal failure; because those whom we most would act thus; and because of a respect for truth. think that a man can obey his conscience without of reward in this world or belief in the next.

To many in our profession the doctor's creed is strengthened by an attempt to believe what to incredible or to accept an explanation which does seem consistent with experience. We prefer to unacceptable hypothesis. To state this is disparage others in and out of our profession who comfort in religious faith.

I can only hope, Sir, that the sincerity of my lett to some extent pardon its obvious presumption.

Manchester.
ROBERT P

Public Health

By-laws for Cleaner Food

THE Minister of Food has issued to local authoriti England and Wales a model for by-laws to secure observance of cleanly conditions in connexion with handling, wrapping, and delivery of food for hu consumption. These by-laws will supplement exist statutory measures. The model has been prepared consultation with local-authority and trade associati

Some desirable provisions have had to be exclu because of shortage of materials and equipment, a the model may be added to from time to time. T suggested provisions, which cover such matters personal hygiene, cleanliness and good order of equ ment, cleanliness of wrapping material, and the dep and removal of refuse, have been drafted with a vi to their application in both urban and rural areas, to every type of food-handling trade. In making laws local authorities are not bound to follow the pre terms of the model, which is intended as a guide provisions which are reasonable and enforceable ha regard to present-day conditions. The Minister h expressed the hope that all local authorities which ha not already done so will consider adopting by-la based on the model.

Births, Marriages, and Fertility in 1947

Part II of the Registrar-General's Statistical Revi for 1947 [1] reveals that in England and Wales the bir rate again rose, illegitimacy continued to decrease, a the stillbirth-rate was the lowest ever recorded in th country up to that time.

Births.—There was 881,026 live births which represent a birth-rate of 20·5 per 1000 total population; this was a increase of 1·3 per 1000 over the previous year and was th highest rate since 1921 when it was 22·4. This post-wa rise in the birth-rate was not maintained in 1948, when th rate fell to 17·9 (provisional). Of the live births, 196 were mothers under 16 years of age, and 16 to mothers aged or over (3 of whom were aged 55 or over). There were 46,0 illegitimate live births, compared with 53,919 the year befor —5·3 and 6·6% of all live births. Stillbirths numbered 21,79 representing a rate of 24 per 1000 total live and still birth compared with 22,915 and a rate of 27 in the previous yea This was the lowest rate recorded up to that time, but it now known that the 1948 rate was 23 (provisional).

---

[1] The Registrar-General's Statistical Review of England and Wal for 1917. Tables. Part II. Civil. H.M. Stationery Offic Pp. 150. 3s.

iages.—In 1947 marriages numbered 401,210—the number since 1940 when it was 470,549. The marriage-er 1000 total population was 18·6, compared with id 18·7 in 1946 and 1945. In 1948 the rate was 18·1 00 (provisional). The most popular age for marrying for men and 21 for women; there were 78 males and males married at the age of 16 years.

lity.—46·9% of the legitimate maternities during the ere to mothers with no surviving previous children: to mothers with one surviving previous child; and to mothers with two. There were 11,221 maternities ng in multiple births, of which 5 were quadruplets and plets. Of about 113,000 confinements which took within 11$^{1}/_{2}$ months of marriage, some 59,000 occurred 8$^{1}/_{2}$ months, and of these about 38,000 occurred 6$^{1}/_{2}$ months.

rces.—The number of decrees nisi made absolute during as 60,190, compared with 30,298 during 1946 and a yearly e of 8288 for the ten years 1936–45.

Vaccination

Exeter, which was ninth on Conybeare's list of sh county boroughs with 28·3% of infants vaccinated. . B. Page, the medical officer of health, believes he number of children being presented for vaccina-s falling steadily. This is happening although the ing steps have been taken:

Almost all the general practitioners in the city have taken to do vaccination and send the completed cates to the health department.

One central weekly vaccination clinic and one fort-y suburban clinic are held in buildings familiar and nient to mothers because they are used for child-e purposes.

Midwives and maternity nurses carry out propaganda home, and there is a definite system of follow-up by visitors.

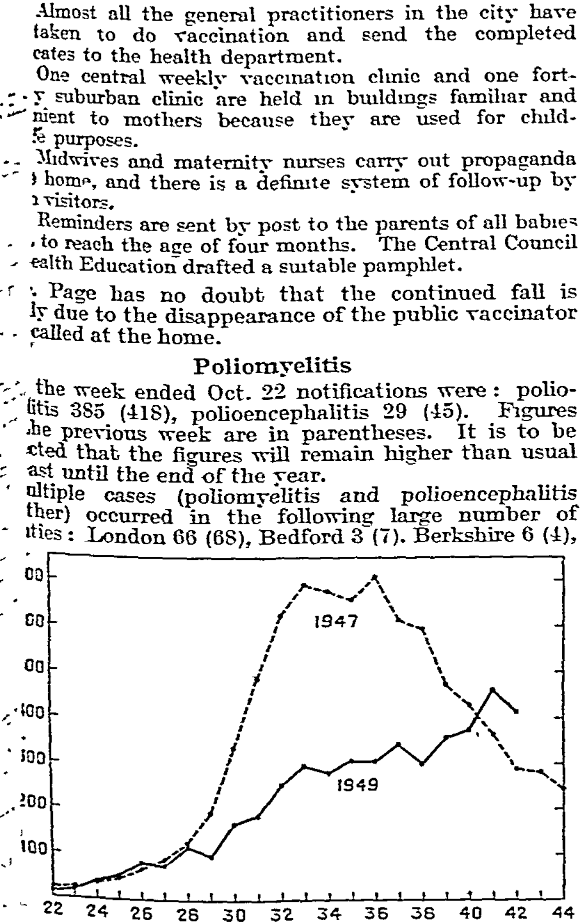
Reminders are sent by post to the parents of all babies to reach the age of four months. The Central Council ealth Education drafted a suitable pamphlet.

Page has no doubt that the continued fall is ly due to the disappearance of the public vaccinator called at the home.

Poliomyelitis

the week ended Oct. 22 notifications were: polio-litis 385 (418), polioencephalitis 29 (45). Figures he previous week are in parentheses. It is to be cted that the figures will remain higher than usual ast until the end of the year.

ultiple cases (poliomyelitis and polioencephalitis ther) occurred in the following large number of ities: London 66 (68), Bedford 3 (7), Berkshire 6 (4), ester 8 (7), Cornwall 4 (6), Cumberland 2 (7), Derby 5 , Dorset 3 (10), Durham 3 (4), Essex 32 (39), Gloucester (21), Hertford 6 (11), Kent 26 (33), Lancaster 25 (32), icester 13 (10), Lincs, Lindsey 7 (0), Middlesex 19 (18), rfolk 8 (8), Northampton 2 (4), Northumberland 9 (3), ttingham 9 (11), Somerset 10 (9), Southampton 13 (10), afford 12 (3), Surrey 16 (14), Sussex, East 2 (4), Sussex, est 2 (2), Warwick 9 (16), Westmorland 2 (0), Wiltshire (8), Worcester 2 (1), Yorks, East Riding 3 (3), Yorks, orth Riding 3 (3), Yorks, West Riding, 47 (48). amorgan 6 (4), Monmouth 4 (1).



Parliament

New Union of Hospital Officers

IN the House of Commons on Oct. 25 Sir JOHN MELLOR raised the question of the refusal of the Minister of Health to negotiate with the National Federation of Hospital Officers. This organisation, he said, was formed in January last year, and registered as a trade union in April. Its membership was confined to administrative, clerical, professional, and technical workers in hospitals and now numbered 3500 out of 6500 workers in this class. An application in July, 1948, for a seat on the functional council for administrative and clerical workers was rejected without any reason being given.

Dr. H. B. MORGAN said that the kernel of this problem was the right of a union, comparatively recently formed, to ask for representation on staff bodies already formed. The new union was of doubtful strength and doubtful permanency. The federation should wait its turn, prove its membership, and ask for representation on the appropriate occasion.

Mr. ARTHUR BLENKINSOP, parliamentary secretary to the Ministry, in reply, said it would be wrong for the Minister to interfere with the staff side of the Whitley Council. The federation represented 3000 out of 22,000 workers, and this number was not sufficient to warrant the Ministry interfering with the existing council.

Economy and the Social Services

In moving a resolution in the House of Commons on Oct. 26 approving the Government's plans to deal with the economic crisis, Sir STAFFORD CRIPPS, Chancellor of the Exchequer, said it now seemed clear that, owing to increased expenditure, the 1949 Budget would not produce as large a surplus as the Government considered necessary. They expected an increase in defence expenditure, that further expenditure would arise in connexion with the improved conditions of service in the health services, and that stocks of materials and foodstuffs would cost more owing to devaluation, or would be greater in quantity. There would be some reductions to offset these increases, and there would still be a large revenue surplus, but it would be considerably less than had been expected.

Giving details of the services to be curtailed, Sir Stafford Cripps said that the charge on the Exchequer for education would be reduced by about £5 million owing to a variety of measures which included an increase in the charge for school meals from 5*d.* to 6*d.* on meals costing 1*s.* 2*d.* and reduced transport facilities for pupils. The reduction of £35 million a year under the head of housing would mean during the course of next year a reduction in the current level of construction from about 200,000 houses a year to about 175,000. The Government considered that the programmes of the local authorities for building houses to let should have priority over the erection of houses by private persons under licence. The further measures required to bring the total saving to the figure the Government thought necessary were: the charge for prescriptions under the N.H.S., yielding £10 million economies; adjustments in the price of some less essential foods, increases in the prices of dried and frozen eggs and raisins, and the removal of the fish subsidy, yielding £7 million; and the elimination of the Exchequer subsidy on animal feeding stuffs, yielding £36 million.

Mr. ANTHONY EDEN, on behalf of the Opposition, said the proposals of the Government had no relation at all to the needs of the hour. Only if we could restore the national economy and confidence in ourselves within the next six months would the later economies have the chance to bear fruit. The Opposition had long urged that widespread economies could be made. The time had come for a thorough review of food subsidies, which in many cases were not subsidising food at all but other things. Not including milk in the schools, and other welfare foods, these subsidies were worth 3*s.* 2*d.* a week to each individual in the country, yet the average weekly expenditure on alcohol and tobacco was 11*s.* 6*d.* The principle of social services ought to be that the strong should help the weak, but we should not try to aid everybody alike indiscriminately.

QUESTION TIME

Births and Deaths Statistics

Mr. J. A. **Sparks** asked the Minister of Health what was the death-rate, birth-rate, and infant-mortality rate at the nearest convenient date and in 1933 and 1938; and by how much the expectation of life had increased compared with 1938.—Mr. A. **Bevan** replied: The figures are as follows:

	Death-rate per 1000 total population	*Birth-rate per 1000 total population*	*Infant-mortality rate per 1000 related live births*
1933	12·3	14·4	63
1938	11·6	15·1	53
1948*	10·8	17·9	34
1949			
March Qtr.*	15·0	17·4	40
June Qtr.*	11·1	17·7	30
Sept. Qtr.*	9·2	16·7	26

* Provisional

	Expectation of life of child at birth	
	Male	*Female*
1938	61·40	65·84
1945	62·56	68·58

Figures for later years are not available.

N.H.S. Prescriptions

Replying to a question Mr. **Bevan** *stated that the number of prescriptions dispensed in England and Wales during the quarter ended June 30, 1949, was about 46 million.*

Choice of Doctors and Patients

Sir **Ernest Graham-Little** asked the Minister of Health *if, in view of his undertaking that there should be free choice of patients by doctors and of doctors by patients, he would state why and under what regulation he assigned patients to doctors, and doctors to patients.*—Mr. **Bevan** *replied:* The power to assign patients to doctors is conferred by regulation 13 of the National Health Service (General Medical and Pharmaceutical Services) Regulations, 1948, made in pursuance of section 33 (2) (c) of the National Health Service Act, 1946. Persons are assigned only at their request.

X-ray Examination of Emigrants

Mr. **Gerald Williams** asked the Minister if intending emigrants requiring X ray were able to obtain this service under the National Health scheme.—Mr. **Bevan** replied: No.

Supply of Artificial Limbs

In answer to a question Mr. H. A. **Marquand** *stated that the average time taken for supply of an artificial leg under the National Health Service was at present 36 weeks. A considerable improvement in the supply position was expected as a result of the recent introduction of two new contractors and the steps which are being taken to increase the output by existing contractors.*

Vitamin-E Therapy

Mr. C. W. **Dumpleton** asked the Lord President of the Council what research was being carried out by the Medical Research Council into the claims made as to the effectiveness of alpha-tocopherol (vitamin E) therapy for heart-diseases.—Mr. **Herbert Morrison** replied: A trial of vitamin E in the treatment of angina pectoris has been carried out with financial support from the Medical Research Council. The results did not bear out the suggestion that vitamin E should be used in the routine treatment of this condition.

Late Claims for Maternity Benefit

Mr. F. J. **Erroll** asked the Minister of National Insurance *if he would extend the period after the birth of a child during which maternity grant and attendance allowance could be claimed.*—Mr. **James Griffiths** replied: *As a result of experience gained in the administration of these claims, the time-limits for claiming have been substantially extended. A month after the birth is now allowed for claiming attendance allowance, and 3 months for maternity grant, with an extension to 6 months in both cases where good cause for the delay is shown. The new time-limits have been given extensive publicity.*

Physique of School-children

Mr. J. A. **Sparks** asked the Minister of Education by how much the physical and nutritional standards of children of school age had improved by comparison with 1938.—Mr. **George Tomlinson** replied: Between 1938 and 1948 the average height of children in England and Wales increased by between $^1/_4$ and $^1/_2$ an inch, and the average weight by about 2 lb. In 1938 the nutrition of 14·5% of children inspected was classified as "excellent" and 74·2% was classified as "normal," the remainder being "slightly subnormal" or "bad." In 1948, under a different classification, the nutrition of 35·8% was classified as "good" and 59·6% "fair," the remainder being "poor."

Obituary

RICHARD ARTHUR NEEDHAM

KT., C.I.E., D.S.O., B.SC., M.D. MANC., F.R.C.S., F.R.C.

Colonel Sir Richard Needham, who died in on Oct. 24, at the age of 72, was known in India able administrator, and in this country as an ob and tactful inspector of overseas medical schools he visited on behalf of the General Medical Council.

Richard Arthur Needham graduated B.SC. in at Manchester, where he qualified as a doctor two later. Among the resident appointments held by was one as house-physician at Manchester Infirmary: and for a time he was a dem anatomy at Owens College. He entered the Ind Medical Service in 1903, and from 1905 to 1908 ser in North China. Four years later, in 1912, he seconded for special duty with the mission for rep tion of Chinese troops from Tibet. In the first war he served in France from 1914 to 1916, whe won the D.S.O. Thereafter he returned to India in 1918 became deputy director-general of med services—a post which he retained until 1924. In 192 he was engaged on special duty in organising the medical services of the Indian Railway Depa In 1923 he had gone to Paris as the delegate of the Office International d'Hygiène publique; undertook a similar mission in 1927. He retired the Indian Medical Service in 1930.

Between 1923 and 1930 Needham had acted as vi of the medical colleges in India approved by the Ge Medical Council; and between 1932 and 1939 he vi medical colleges in Rangoon, Ceylon, and Hong-K In 1939 and 1940 he undertook, on behalf of the Col Office, a similar review of the medical schools of Ni and Uganda. He served on the council of the Br Medical Association from 1932 to 1938. In the se world war he was commissioner of the Red Cross [illegible] Middle East and Italy; he [illegible] r of St. John of Jerusalem. [illegible] C.I.E. in 1919 and created a kn in 1932. He graduated M.D. in 1920, and bec F.R.C.P.E. in 1924 and F.R.C.S. in 1940.

C. H. B. writes: "To very many 'batches' of old I. men the passing of 'Dicky' Needham will almost symb the passing of the old I.M.S. as we who are left kne 'Dicky' to us meant the D.G.'s office, for when one went up to Simla or to Delhi, on purpose o leave, one called on the Director-General of the Se and was always sure of a welcome and an inter chat with the D.G.'s deputy, even if he turned d anything you might be asking for; and we all liked respected him and admired his efficiency during the war years when he held that post. D.G.s came went but Needham seemed a fixture and was the who knew all about you and was largely respon for your destiny in the Service. Despite this he had enemies and certainly many friends and they wil mourn his passing. In later years after he ceased deputy, one met him from time to time, generally at old East India U.S. Club, or at the I.M.S. dinner. the former occasions he usually seemed to have returned from some distant part of the world wher had been organising State medical services, or in national hygiene, or the Red Cross. He led, I thin jolly life. On these peregrinations he met many ac and interesting people and enjoyed it all. He wa great organiser and a robust and likeable persona whose cheery presence and sound talk we shall sadly mi

Another personal tribute comes from S. R. C. who sa "Though not in the Indian Bacteriological Serv Needham was always a welcome visitor to any of laboratories he had occasion to visit. Genial and frien he was always helpful and stimulating, and those of Service who had occasion to attend meetings or had ot business in Simla he went out of his way to make welc guests at his house, and by his friendly hospitality make their visit a pleasant experience. Needham ha flair for diplomatic work and was an active particip in many fields where this characteristic found full p He was keenly interested in all to do with the Ind l Service and was a great supporter of its interests. arried in 1925 Harriet Ellen, daughter of Lieut.- l R. Dewar, R.A.

CHARLES OLIVER HAWTHORNE

., LL.D. GLASG., D.SC. MANC., F.R.C.P., F.R.F.P.S.

C. O. Hawthorne, who died on Oct. 24 at the age had found time during his long life for several careers. He had practised medicine as a consultant gow and London; he stood high in the counsels British Medical Association; he was a pioneer tgraduate medical education; and he wrote and with erudition and fluency on questions of public .

884 he graduated M.B. with first-class honours at niversity of Glasgow, and three years later he ppointed assistant to the professor of the practice licine, a post which he held for the next ten years. as also clinical tutor at the Western Infirmary, w, later becoming assistant physician. In 1890 k the F.R.F.P.S. by examination and in 1899 he ded to the degree of M.D. which he obtained with ass honours. He was awarded the gold medal for sis. He also held a lectureship on materia medica erapeutics at Queen Margaret's College, Glasgow. e examined for the universities of Aberdeen, urgh, and Glasgow. To this period also belong his oks on *Galenical Preparations of the British acopœia* and *Forensic Medicine and Toxicology*.

London, where he settled in consultant practice, ckly won recognition and was appointed to the of the Hampstead and North-West London General tal, the Royal Waterloo Hospital, the Central n Ophthalmic Hospital, and the Central London tal for Diseases of the Nose, Throat, and Ear. 1909 to 1914 he was medical director and chairman e council of the Medical Graduates College and linic. In 1912 he published his *Studies in Clinical ine* and in 1928, in his *Short Essays on Medical s*, he gave a sane and balanced judgment on ems encountered in his long professional life. In he was elected F.R.C.P. His own university also wed on him the honorary degree of LL.D., and hester awarded him a D.SC. He especially valued honorary fellowship which he received from the l Academy of Medicine in Ireland.

member of the B.M.A. since 1888, he served on many s committees, though his interests were perhaps closely bound up with the work of the ethical, ce, and charities committees. From 1928 to 1931 resided, with outstanding ability, over the Repre- itive Body. “The thing that impressed one most his quite remarkable power of diction; his choice ords was almost perfect; and he was able to convey eaning in a way that impressed all who heard him. charm of his manner was great, and while he was an ive and indeed merciless opponent in argument, ever failed to encourage the lesser man; indeed ent out of his way to do so.” In 1932 he was elected e-president of the association, and in 1939 he was ded its gold medal.

r. Hawthorne gave much time and thought to medical ities, and was a valuable member of the Royal ical Benevolent Fund's management committee, which he often presided. As chairman of council he People's League of Health he worked stead- ly for the league, and he took an important part in its iry into maternal mortality and nutrition. In he was a member of a medical deputation to Ministry of Health to discuss safeguards for our -supply.

ARTHUR HILL BURNETT

M.R.C.S.

r. A. H. Burnett, who died on Oct. 7 at the age of 68, born in Southampton, and was educated at King ward VI School and the old Hartley College. He eived his medical training at Edinburgh University the London Hospital, qualifying in 1904. After ding house-appointments in London he visited many ts of the world as ship's surgeon. During the 1914–18 he served in the R.A.M.C., with the rank of tain.

In Southampton outside his busy practice he gave a large part of his time to the administration of anæsthetics: in 1919 he was appointed anæsthetist to the Royal South Hants and Southampton Hospital, and medical officer to St. Mary's Institute. At the Royal South Hants Hospital he was recognised as being an expert anæsthetist, and on retiring from this post during the late war he was appointed honorary consultant anæsthetist to the hospital. “He was an able physician and the pleasantest of colleagues. His contemporaries will long remember his ever-happy disposition, sincerity, and great friendliness.”

JOSEPH EDWIN BARNARD

F.R.S.

Mr. J. E. Barnard, formerly honorary director of the department of applied optics at the National Institute of Medical Research, was perhaps as close an example as this age affords of the distinguished scientist to whom science is a leisure pursuit. His father, the owner of a well-known hatter's business in the West End of London, gave his son only the education which he thought a suitable preparation for the family business. When the young Barnard left school he had shown two aptitudes —for music (he played the organ in the Methodist chapel which his parents attended), and for natural science. His father gave him a 3-guinea microscope when he was 16, and later looked on this as the only mistake he made in his son's education, since it led him to centre his interest on the useless hobby of microscopy instead of on the proper business of making and selling hats. Concluding that he could run only one hobby outside his work, the boy decided on microscopes rather than music; and at this stage he received encouragement from the Rev. W. H. Dallinger, F.R.S., a Methodist minister who had achieved distinction as an amateur scientist and was much in request as a lecturer—young Barnard assisting him with photography and lantern-projection. Before long he was working in several centres of medical and scientific research, including King's College, London, and he became known and appreciated by J. A. Murray, the late William Bulloch, and Leonard Hill. Eventually he was given accommodation, with a grant for assistance and expenses, at the National Institute for Medical Research when this opened at Hampstead in 1920, and his unit developed into a small department of optical and physical methods.

Barnard was then developing, with coöperation from the microscope industry (Messrs. Beck especially), an apparatus for photomicrography with ultraviolet radiation, using a system of quartz lenses. This was elaborated over a period of years, its ultimate form using a single wave-length in the shorter range of the ultraviolet. He was thus able to carry sharp resolution to objects of no more than half the size of those previously demonstrable by microscopy using visible rays. The extra range thus obtained seems curiously small now; but there can be no doubt that his work played a very important part in establishing the fact that the “elementary bodies” of a number of the true viruses could be rendered sharply visible by photography, without staining, and that their dimensions, as so measured, corresponded with those of the infective units of the same viruses as measured by selective ultrafiltration by W. J. Elford, working then as a member of his department. This work of Barnard's had also a pioneering quality, in revealing the possibilities open to photomicrography with invisible radiations, which have now led to the much higher resolutions obtainable with the electron microscope. Anybody who made close contact with him at that period would have had the impression that even such advanced developments were almost on the horizon of his scientific ambition, and were denied to him only by an education which had not given him the requisite background of knowledge in the fundamental sciences. With early advantages he might have gone even further as an inventor and discoverer. His energies, too, remained divided, for to the end of his activity in science he gave only half of each day to such research, and the other half to his business. Yet if he needed precedent he could have pointed to previous microscopists and fellows of the Royal Society, from the time of Leeuwenhoek, draper of Delft; and it is possible that his services to his science, and indirectly to medicine, might in fact have been no greater if he had exchanged his amateur status for that of the professional.

Mr. Barnard died at his home at Addiscombe on Oct. 25, at the age of 80.

JOSEPH EVERETT LA FRENAIS

L.R.C.P.E.

Dr. J. E. La Frenais, of Runcorn, Cheshire, died on Oct. 2, while on holiday in Scotland. He was educated at Dollar Academy, and studied medicine at Edinburgh, qualifying in 1930. He later held house-appointments at Hull Royal Infirmary and at Chester Royal Infirmary, where he became acquainted with the county in which he finally settled in 1935. During the late war he served in the R.A.F., reaching the rank of wing-commander. His service in the East left him with the disability which led to his death at the age of 44. On leaving the R.A.F. he resumed his practice, in partnership with his brother and later his brother-in-law. Although a bachelor himself, he was especially fond of his young patients, who instinctively responded to him; but his friendliness and kindness attracted patients of all ages. A Freemason and a Rotarian, he was also associated with the Runcorn squadron of the A.T.C., and at the time of his death he was the captain of Runcorn golf-club.

OTTO KAUDERS

From 1915 until his death on Aug. 6 at the age of 56, Dr. Otto Kauders held the chair of neuropsychiatry in the University of Vienna, made famous by his teacher and colleague Wagner-Jauregg. His productive life was hampered by political persecution and war. After serving as a medical officer in the Austrian army during the first world war, he was appointed to the neuropsychiatric clinic of the university of Vienna, where he later became Wagner-Jauregg's first assistant. In 1935 he was appointed to the professorship of neuropsychiatry at Graz. But with the spread of National Socialism in Austria he lost his appointment at Graz and took up consultant practice in Vienna. In 1939 he visited the United States; but he returned, with commendable courage, to see the second war through in his own country. In 1945 he was reinstated at Graz in July, and the following month he was appointed to the chair in Vienna.

In his earlier papers Kauders wrote on the psychiatric sequelæ of epidemic encephalitis, the internal secretion of the testis, and, with Wagner-Jauregg, on inoculation malaria. Later he essayed the malarial treatment of poliomyelitis and was hopeful of its usefulness. With Schilder in 1926 he published a textbook on hypnotism. Since the war he had done much to reorganise his own specialty in Austria. He started once more the *Wiener Zeitschrift für Nervenheilkunde*, of which he became editor-in-chief. His other writings include papers on the vegetative nervous system in relation to psychosomatic medicine, towards the study of which he was directing his department at the time of his death. He visited America for a third time in 1949, and in 1948 he led the Austrian delegation to the International Mental Health Congress in London.

R. W., an English colleague, adds: "Otto Kauders hid a firm character under the grace and charm of a cultured Austrian gentleman and patron of the arts. Not a Jew but a faithful Roman Catholic, he uncompromisingly endured a political persecution which he could easily have avoided, and acted, without melodrama, the part of a citizen prepared to resist wrongful government, alone if need be, and if need be to the death. I have a vivid impression of him in 1946, erect and still youthful, immaculately dressed, lunching off stale bread and water before his ward-round in the Allgemeine-Krankenhaus. His plea then was for a more sympathetic understanding from the 'Liberators' for the character of his younger colleagues and assistants, hard worked, half starved, and devoted. I can pay a tribute to the leadership he gave them then and to his own sterling character. For more than one visiting student of medicine he typified the most gentle yet most dignified of Austrian attitudes in the face of fourfold disaster. Withal his mind was wide open to the future."

Notes and News

CHLOROMYCETIN IN TYPHOID FEVER

In Sweden, Gabinus[1] has observed the effect of ' mycetin ' in seven cases of typhoid fever which admitted to hospital at Jönköping during the past a further two cases had perforce to serve as control the drug was scarce. All seven of the treated rendered afebrile after about 3 days, whereas the two remained febrile for 4 weeks. Chloromycetin was tered for only 3–10 days, and two of the relapsed with bacteræmia after the temperature had normal for 12–14 days. Gabinus quotes Bradley[2] that no definite opinion of the mode of action of in typhoid fever can be formed until the effect of during the first week of the disease has been This condition was fulfilled in three of the Swedish In one of these blood-culture, undertaken because member of the patient's family had already developed fever, was positive for 4 days before the patient any symptoms; but each of twelve cultures while chloromycetin was being given was negative. of these negative results were obtained with blood only a few hours after the start of treatment; and suggests that the rapid change from positive to was due to the presence of chloromycetin in the blood —in other words to the antibiotic action of the drug culture. He also suggests that the drug may effective preventive of the carrier state.

ROYAL DENTAL HOSPITAL

The 33rd annual clinical At Home of the school wa on Oct. 29. Any dental surgeon could have found lecture or a demonstration on his pet subject, was conservative treatment, denture work, or mino surgery. Obviously all departments had worked have interesting and out-of-the-way cases on view. morning session, which included two lectures and a demo tion of speech therapy, ended with the formal open the Stobie Memorial Library by Dame Lilian Lindsay

The highlight of the day's programme was a tele demonstration arranged by Marconi's Wireless Telegra Ltd. A 625-line closed-circuit system linked the ope theatre to the lecture hall. An 'Image Orthicon' cam the theatre transmitted by wire to four receivers in the only three of these—two with 9 in. tubes and one 15 in. tube—were seen by the audience, as the fourth used by the engineers for monitoring the transmission a permanent installation, these would be replaced projection-type tube which could throw a picture 5 ft. square. The morning demonstration was give Mr. Bowdler Henry, and a frenectomy was among operations televised. In the afternoon, Dr. A. showed how easy the removal of buried teeth can the hands of an expert; a lively commentary on the ope was given by Dr. H. M. Pickard, assisted by Dr. MacC himself. The television camera, with its four-lens made it possible to see each step of the operations as p as the operator himself saw it. The definition of the p was excellent—better, in fact, than with the average tograph film—although the contrast between different was not always as clear as could be wished. All the a small root apex, which gave some trouble before it finally removed, could be distinctly seen from the b the lecture-hall.

The last item in the At Home was a well-made and h teaching film in colour on the technique of Scaling Polishing.

LONDON HOSPITAL DINNER

Many medical dinners are dominated by their environ the restaurant and the toastmaster make the diners unnatural if not superfluous. But, whether by weig numbers or otherwise, the old students of the London Ho have always contrived to make their annual dinner a genu London Hospital occasion—homely and in character. year they reverted to the Trocadero, where they used to before the war, and some 340 of them enjoyed a long, cursive, easy speech by Sir Eardley Holland, the chair on the year's events and people in the hospital and me school. Having spoken with deep regret of the deat

ity of Oxford

amination will be held at Worcester College, beginning 3, 1950, for the purpose of awarding a Nuffield medical ip of the value of £100 a year, tenable for four years. rms should be returned to the Provost of Worcester not later than Dec. 10.

ity of Cambridge

aymond Horton-Smith prize for 1948–49 has been to Dr. J. R. Squire.

ity of London

orrest Fulton has been appointed to the readership riology and immunology at the London School of and Tropical Medicine.

lton, who graduated as B.M. Oxfd, in 1939, is a member entific staff of the Medical Research Council in the depart- bacteriology and virus research at the National Institute al Research in Hampstead. During the war he worked M. Begg on the relationship of the murine and epidemic rickettsiæ, and their relationship with proteus OX 19. member of a team which investigated different laboratory of estimating the potency of typhus vaccines and he was or of the report to the Medical Research Council in 1946 *otherapeutic and other Studies of Typhus*. Previously he ed on diphtheria immunisation, staphylococcal toxins, and diarrhœa. Dr. Fulton took his D.M. in 1945.

itle of professor emeritus of physiology has been d on Dr. C. A. Lovatt Evans, F.R.S., on his retirement e Jodrell chair at University College which he had e 1926.

ollege of Physicians of London

comitia of the college held on Oct. 27, with Lord the president, in the chair, Dr. E. C. Dodds was Harveian librarian. Dr. Terence East, Dr. N. B. Sir Horace Evans, Dr. J. G. Scadding, and Dr. T. F. e elected councillors. The following representatives cted: Dr. C. M. Hinds Howell on the Committee of nent; Dr. F. S. Langmead on the Central Midwives the President, Sir Leonard Parsons, Dr. H. E. A. , Dr. W. G. Barnard, and Sir Allen Daley on the g Joint Committee of the three Royal Colleges; ds Howell, Dr. T. C. Hunt, Dr. J. C. Hawksley, and B. Harman on the Committee of Reference; and ds Howell and Dr. Harman on the Central Medical mmittee.

following were elected additional examiners for the ship examination:

inds Howell, Dr. C. E. Lakin, Dr. Anthony Feiling, Dr. Ward, Dr. Terence East, Dr. Hugh Gainsborough, Dr. Hunter, Dr. Macdonald Critchley, Dr. W. Russell Brain, rice Shaw, Dr. W. E. Lloyd, Dr. Kenneth Harris, Dr. Elkington, Dr. T C. Hunt, Dr. Clifford Hoyle, Dr. J. G. , Dr. McL. Rosenheim, Dr. Horace Joules, Dr. F. Avery

. C. Broom was appointed Milroy lecturer for 1951, ject being Leptospirosis. The Jenks scholarship was d to B. R. Wheeler, late of Epsom College.

ollowing were elected to the membership:

Aitchison, M.B. Glasg., L. S. Antonoff-Lewis, M.B. N.Z., aldry, M.B. Lond., T. B. Binns, L.R.C.P., M. I. Bostock, fd, D. P. Bowler, M.B. Lond., R. E. Britten Jones, M.D. , P. H. Buxton, M.B. Peake, Dorothy J. Pearse, A. M. Platt, H. R. Playfair, D. F. Potter, G. L. Powell, J. M. Price, D. C. E. Rabbin, Rebe S. Rainsbury, Olga M. Rampersaud, Stella J. E. Randall, F. G. Reader, Michael Reckless, V. E. Rees, Joyce M. Richardson, J. J. Ridealgh, K. H. Ritchie, Nigel Rivers, J. S. Robertson, Yvonne K. Russell, Mark Sackwood, J. G. Sahakian, C. M. Samuel, J. T. Scott, J. D. Shapland, E. W. Shepherd, E. A. D. W. Simpson, W. K. Slack, G. H. Smerdon, Margaret W. H. Smith, A. W. Sonia, Gwendoline R. Stockley, W. H. J. Summerskill, A. S. Szurkawski, D. H. C. Thomas, Olwyn K. Thomas, O. L. Thomas, K. D. B. Thomson, N. A. Toes, Arthur Trueman, B. S. Turner, C. A. Unsworth, J. T. Wallace, D. E. Wallis, Glyn Walters, A. W. S. Webster, I. M. Wedgwood, B. L. Whitaker, Rodney Wilkins, S. W. Wilkins.

Diplomas were conferred on those named in the report of the Royal College of Surgeons (*Lancet*, Oct. 22, p. 773). The D.O.M.S. was also conferred on J. H. Owen-Flood and the D.T.M. & H. on T. H. Work.

National University of Ireland

The following awards have lately been made: travelling studentship in pathology to Dr. D. S. Breen; travelling studentship in anatomy to Dr. L. G. O'Connell; bursary in surgery to Dr. W. H. Radley.

Sherrington Society

A group of students of Liverpool University, who have taken an honours B.SC. course in physiology and who are now continuing their studies in clinical medicine and dentistry, have formed this society for the discussion of problems common to clinical medicine and the basic sciences. The first meeting was held on Oct. 19 when Sir Henry Cohen spoke on Pain. The next meeting will be held on Wednesday, Nov. 9, at 7.30 P.M., in the physiology lecture-theatre of the university when Prof. A. C. Frazer will describe Studies of Normal and Abnormal Fat Absorption in the Human Subject.

Pharmaceutical Society of Great Britain

At 17, Bloomsbury Square, London, W.C.1, on Thursday, Nov. 10, at 7.30 P.M., Mr. T. C. Denston, F.R.I.C., deputy secretary to the British Pharmacopœia Commission and formerly editor of the *British Pharmaceutical Codex*, will speak on the *British Pharmaceutical Codex 1949*.

Memorial to Dr. Slome

On Oct. 26, at the London School of Chiropody, Mr. A. M. A. Moore, F.R.C.S., president of Board of Registration of Medical Auxiliaries, unveiled a plaque in memory of Dr. I. S. Slome, director of studies at the school from 1936 to 1948.

Bequests by the Late Dr. Barclay

Dr. A. E. Barclay, whose estate amounted to £79,000, left £3000 to the British Institute of Radiology, and books and equipment to the Nuffield Institute for Research at Oxford. Subject to a life rent, shares in the residue of his estate are to go to the Strangeways Laboratory, Cambridge, the Royal Medical Benevolent Fund, and Papworth Village Settlement.

Eric Guttman Memorial Trust

A trust in memory of the late Eric Guttman was founded recently by his widow, Dr. Elizabeth Rosenberg. The purpose of the trust is:

To further the development of the Guttman-Maclay collection of pictures and books related to art and psychiatry;

To help the medical staff of the Bethlem Royal and Maudsley Hospitals (other than staff of consultant status) to attend scientific meetings and conferences; and

To furnish loans to young psychiatrists to further their training.

Further particulars may be had from the trustees, Maudsley Hospital, Denmark Hill, London, S.E.5.

Wessex Rahere Club

The second annual dinner of this club was held at Bath on Oct. 15, when Sir James Paterson Ross was the guest of honour and Mr. C. E. Kindersley was in the chair. Barts men living in Wessex who wish to join the club should write to the hon. secretary (Mr. A. Daunt Bateman, 3, Circus, Bath).

New Occupational Therapy School

The Derby School of Occupational Therapy—the seventh of its kind in the country and the first forming part of the National Health Service—was opened on Oct. 27 by Dr. Harold Balme, of the Ministry of Health's rehabilitation and resettlement department. The school, which gives a three-year course in conjunction with the Derby School of Arts and Crafts, will take at least sixty students.

Administration of Mental Hospitals

Hospital authorities have been advised by the Ministry of Health that the medical superintendent of a mental hospital or mental-deficiency institution, being the chief officer and responsible for general management, should see a copy of all relevant documents issued to the hospital management committee by the Ministry or by the Board of Control. It is also pointed out that the Minister laid down certain standards of accommodation in mental hospitals and mental-deficiency institutions, in order to secure special precautions and conditions essential for patients and staff. The authorised accommodation has been specified in the case of every institution; "and it is essential that no variation in the use of this accommodation should be effected without the knowledge and approval of the Department."

Prof. Alan Moncrieff is returning next Thursday from a ten-day tour of Portugal, where he is lecturing on behalf of the British Council.

Appointments

BENTLEY, J. P., M.B. Lond., F.R.C.S.: consultant general surgeon, Harrow Hospital.
BODENHAM, D. C., M.B. Brist., F.R.C.S.E.: asst. plastic surgeon, Frenchay Hospital, Bristol.
HUGHES, WILLIAM, M.D. N.U.I., M.R.C.P., D.T.M.: geriatrician, Bristol clinical area.
LYON, D. M., O.B.E., M.B. Edin., D.P.H.: deputy county M.O.H. and deputy school M.O., Kent.

11 A.M. (London School of Hygiene, Keppel Street Symposium on the Biological Oxidation of Rings.

Births, Marriages, and Deaths

BIRTHS

GRANT.—On Oct. 22, in Birmingham, the wife of Mr. R. F.R.C.S.—a daughter.
HEWER.—On Oct. 21, in London the wife of Dr. A. J. H a daughter.
KINMONTH.—On Oct. 26, in London, the wife of Mr. John F.R.C.S.—a son.
LLOYD.—On Oct. 22. the wife of Dr. J. T. A. Lloyd—a da
MACRAE.—On Oct. 26, at Ilford, the wife of Dr. A. D. a daughter.

MARRIAGES

ANDERSON—HARVEY.—On Oct. 26, at Cadleigh, near J. Tardrew Anderson, M.B., to Anne Harvey, M.B.
COOPER—LEACH.—On Oct. 25, at Rochdale, Lancs, Willi Cooper to Joyce Leach, M.B.
GREEN—WHITE.—On Oct. 21, at Aber, David Mitch M.B., to Elizabeth White, M.B.

DEATHS

HAWTHORNE.—On Oct. 24, at Hove, Charles Oliver M.D. Glasg., D.SC. Manc., F.R.C.P., F.R.F.P.S.
NEEDHAM.—On Oct. 24, in London, Richard Arthur KT., C.I.E., D.S.O., M.D. Manc., F.R.C.S., F.R.C.P.E. brevet colonel I.M.S., retd, aged 71.
ROGERS.—On Oct. 28, in London, Norman Cumming M.B. Glasg.
WOODS.—On Oct. 23, at Douglas, *Isle of Man*, Lionel Woods, O.B.E., L.R.C.P.I., aged 63.

MATERNAL OBESITY*

J. H. SHELDON
M.D. Lond., F.R.C.P.
DIRECTOR OF MEDICINE,
THE ROYAL HOSPITAL, WOLVERHAMPTON

E purpose of this lecture is to call attention to the est of a common syndrome, which has been strangely cted by clinicians. It is a matter of common vation that women may at times develop a severe ty after having a baby, but the details of this ss have not been worked out and its only clinical iptions appear to lie in occasional requests from itioners for information on its treatment.[3-5] Nevertheless these details pose some remarkable problems.

e account which follows is based on the study of 40 en who had developed obesity in relation to the of one or more of their 109 children, while for rol purposes 40 women were studied who had no equent gain of weight after the birth of their 119 ren. I should emphasise at the outset that the ription is tentative only, and not definitive; for it ar that further studies on a larger series are necessary, that they should be undertaken while the gain of ht is actually in progress and therefore capable of t measurement.

TOTAL GAIN OF WEIGHT

f the 40 women, 38 knew their marriage weight; so total gain of weight could be estimated with some racy. The results are shown in table I.

would be fallacious to draw conclusions from the ibution of weight gain shown in this table, for the en represent a special sample referred to me by titioners of the district in response to a request for cases. Since only the obvious ones were sent—ved in the main from those who had actually consulted r doctor on account of obesity—it is impossible to whether they represent a separate entity or, as is e probable, they are merely the extreme examples process varying continuously from no gain up to maximum shown. The importance of the table lies s demonstration of the sheer size of the weight gain may be undergone by some women, for exactly the group had gained 75% or more on their marriage ht, and 4 cases had more than doubled this weight, maximum figure being a gain of no less than 125%. two severest cases were:

) A woman married with a weight of 8 st. 1 lb. She me extremely fat during her first pregnancy and weighed ly 14 st. at the end of the lying-in period. There a similar gain during the second pregnancy, followed slow rise to her present weight of 18 st. 7 lb.—or a gain 23%.

) A woman married with a weight of 9 st. She has two children, in each case with a rapid gain during nancy followed by a slow rise afterwards to her present ht of 20 st. 4 lb.—or a gain of 125%.

PROGRESS OF THE WEIGHT GAIN

wo or more phases could be distinguished in many of cases: (1) an initial phase, characterised by a rapid gain of weight; (2) a phase of equilibrium in which the weight remained perhaps indefinitely at its new high level; (3) an occasional phase of decline in which some or all of the superfluous weight was lost. The initial rapid phase appeared occasionally to be replaced by a slow steady gain continued for some years.

Initial Phase

This was characterised in typical cases by a very rapid gain of weight which began abruptly and either ended abruptly or gradually slowed in rate as the weight approached its final stationary level. Sufficient details were available from 16 women (19 confinements) to provide an indication of the actual rates of weight increase operative during this period. These are shown in table II.

The occasions on which these women had weighed themselves were entirely haphazard, but the table is nevertheless instructive. It will be seen at once that the longer the interval the smaller was the average rate of gain, for which there may be two explanations, based on different modes of increase. In the one there was an extremely rapid initial gain, as in case 25—when this woman's second baby was 11 days old she weighed 133 lb., and on the day it was 8 weeks old she weighed 170 lb., so she was gaining at no less than 5 lb. per week for a short period. In those patients who had weighed themselves within a year of the confinement the average rate of gain was 2 lb. per week, and in some of these there was a slow subsequent gain. Thus case 15 rose from 133 lb. at her confinement in January, 1940, to 168 lb. in April, 1940 (2 lb. per week), and over the next four years she rose to 218 lb. (0·25 lb. per week). The rate for the whole period would be 0·4 lb. per week, which is similar to those of cases 1, 5, and 3, who only knew their weights over intervals of about four years, and suggests that in them also there may have been a steep initial gain followed by a slow subsequent rise. The other mode of increase appeared to be a slow steady one: although 11 of the women represented in the table had been conscious of a rapid phase, 5 denied its existence and were emphatic that they had merely had a slow steady rise following the birth of the baby. It is clear that the rate of increase may be as remarkable as the final weight achieved. The case-histories suggested that this rapid gain of weight might begin in relation to two modes of variation:

(*a*) Either during pregnancy or immediately after the confinement.

(*b*) As a response either to one particular pregnancy or to all pregnancies.

These two variables were well mixed, but on the whole women who gained weight with each baby tended to notice the obesity during the pregnancy.

ing a lecture delivered to the Postgraduate Medical School of London on Oct. 31.

ICAL DEP

(*a*) 21 of the 40 women stated that they first noticed the obesity during the pregnancy, but the changes so set in motion continue after delivery, for in 19 of these women the weight continued to rise afterwards. The onset was sufficiently sudden for them to be able to date it to a particular month of pregnancy, which in the majority of cases lay between four and a half and six months, though it might be as early as the second month, and one woman noticed it in the first month. 19 women, however, were *convinced that they did not begin to* develop obesity till after the confinement, and in such cases it may be that the gain of weight arose in relation to the establishment of lactation. Confirmation of this postpartum onset of obesity was obtainable in many cases from the clothes worn by the women, the story being frequently told that on getting up from bed they could not even wear the clothes they had worn immediately before the confinement.

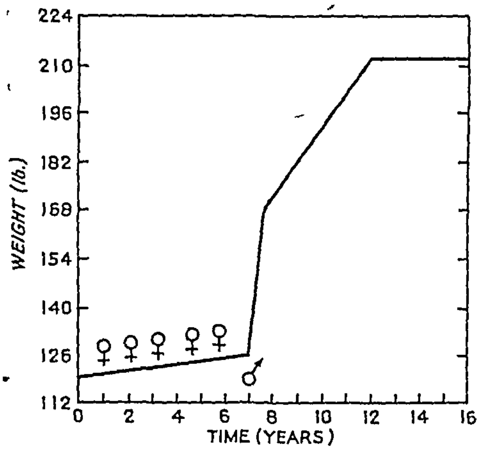

Fig. 1—Obesity after a particular pregnancy.

Thus one woman wore stock size "small women's" clothes during pregnancy, which she let out as required. This is confirmed by the fact that she weighed herself when eight months pregnant, and was 7 st. $8^1/_2$ lb. Two days later *she was confined with a premature baby weighing* $3^1/_2$ *lb.* When she came to get up she found that none of her clothes would fit her and her mother had to go out and buy some temporary second-hand clothes. She insisted on having her own clothes to attend the christening of the baby, which took place three *weeks after the confinement, and found* that the only ones she could get into were stock O.S.—or "outsize clothes." The baby was born eighteen years ago, and she has had to wear this size since.

A woman married at the age of 18 with a weight of 8 st. 2 lb. After her first baby there was no change in weight and she wore the same clothes as before the pregnancy. During the second pregnancy she only had to change her clothes at the end—the baby was small and weighed $5^1/_4$ lb. After the confinement she was in bed for three weeks, and when she got up she had become so fat that she could not even get into her maternity clothes, and had to have a new outfit. Thereafter she had to have a new set of clothes every month for nine months, by which time she had doubled her weight to 16 st. Her weight and clothes have remained stationary at this level for fourteen years. Several patients provided similar histories, which furnish strong evidence both of the postpartum onset and of the permanent nature of the weight gain.

(*b*) The other mode of *variation was in relation to* particular pregnancies. In one type, the obesity was the result of a single particular pregnancy, while in the second type each successive pregnancy caused a smaller gain of weight, which therefore rose in a series of steps. It was not always possible to distinguish the two types, for the second would not be apparent if there was only one pregnancy; and if the gain continued over some years, and there were further children during this period, it might be attributed *to them whereas it was really a* continuous process dating from the prior pregnancy. Nevertheless the distinction was apparent in some cases, and its reality is supported by extremely curious differences in the babies.

The weight curves of two women in whom the
was clear are shown in figs. 1 and 2.

Fig. 1 represents a woman who married with a weight 8 st. 7 lb. After giving birth to five girl babies in the six years, she began her sixth pregnancy with a wei 9 st. After the birth of her first boy baby she gained in the next four months ($2^1/_2$ lb. per week) and then gained a further 42 lb. over the next three years, to a weight of 15 st. 2 lb. Whereas the first five had only caused a total gain of 7 lb. the sixth to a gain of 6 st.

Fig. 2 represents a woman who married with an weight of 10 st. After her first baby—a premature weighing 3 lb. 3 oz. she gained weight rapidly and 13 st. in the next four or five months. She remained at this weight for ten years, when after a second rose to 14 st., and again remained stationary for three when after a third baby the weight rose slowly to 15 st. at which she has remained for seven years.

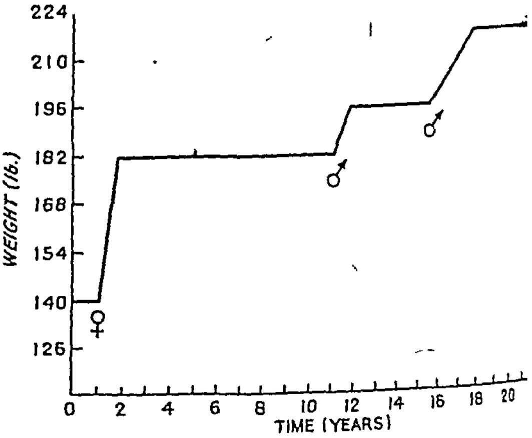

Fig. 2—Obesity after each pregnancy.

The second type almost invariably began with first baby and further gains occurred *with each* additio child. In 17 of the 18 cases placed in this group it after the first baby, and in the other it was the sec pregnancy. By contrast, the first type may not app *till a late pregnancy.* 13 of the 22 cases placed in group began after the first pregnancy, 6 after the seco 2 after the third, and 1 after the sixth. Almost invaria these later cases did not occur till a boy baby was bo the preceding babies having been girls. In fact, of 22 babies responsible for the onset of the condition this type, no less than 18 were boys and 4 were girls. the second type, where gain occurred with each pregnan the sex of the baby made no difference, there being boys and 37 girls in the 65 *children concerned.* In addit there were curious differences in the weights of the ba born to these various groups, which are dealt with la

Phase of Equilibrium

This is *a state of equipoise in* which the weight rema stationary at its new high level, and may last indefinite Occasionally a very slow rise might continue during t period—as in one case where the weight increased one stone over thirteen years, and in another by 10 lb four years. If the weight is reduced by diet or thyr treatment during this period, it tends to return to old level if the treatment is stopped.

Phase of Decline

In most cases the static phase appeared to per indefinitely, but occasionally the weight later decreas or even returned to its old level. Thus in *one case* wh the weight had been almost stationary for ten year rapidly fell after a further pregnancy, and in two ye the woman lost all the weight she had previously gain Subsequent loss of weight stood place in only 4 of t 40 cases—2 without discoverable cause, 1 *after* pregnanc and 1 after an emotional upset.

INSTABILITY OF WEIGHT CONTROL

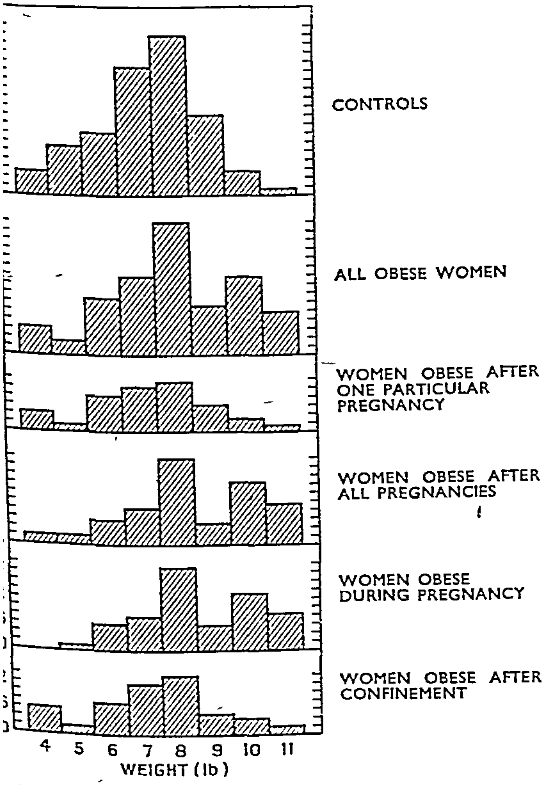
certainly curious that the same process of weight ay be initiated either during or immediately egnancy, and it is equally curious that the process rsist in operation for years after the immediate as ceased. The records of some of the cases that an instability of weight control is produced ys in the upward direction in the cases under ion—which may remain active for long periods.

a woman was 12 st. when her third baby was born At the end of the lying-in period none of her clothes it her and she had to borrow from a relative. She rapidly for a short time and then slowly increased, in March, 1949, she weighed nearly 15 st., when she herself again rapidly putting on weight. From 26 to May 28, 1949, she therefore weighed herself at ist's at weekly intervals—the successive increments lb. 6 oz., 3 lb. 13 oz., 2 lb. 10 oz., 2 lb., 7 lb. 10 oz., oz., 6 lb. 6 oz., 5 lb. 8 oz., 2 lb. 6 oz. She therefore 41 lb. 3 oz; in nine weeks, rising from 15 to 18 st., is volcanic increase occurred as a termination to a s slow gain, for after that her weight remained ry, 50% above its starting-point.

other case a woman married at the age of 27 with a of 10 st. She has one child aged 4 years 9 months. an to put on weight immediately after the birth and a slower rate so that in three and a half years she 14 st., but during the next fifteen months she increased stone. For the first period, therefore, she increased verage of 0·3 lb. per week, and during the second at per week.

CLINICAL CHARACTERS OF THE OBESITY

great majority of cases had a generalised obesity t special features. The deposits of fat tended to ulate especially on the proximal half of the arms, easts, abdomen, buttocks, and thighs, and in the dvanced cases this localised adiposity became very able. In the whole series of 40 cases there were only unusual features: 1 had other features suggestive of a Cushing's syndrome and 4 had an obesity virtually limited to the lower half of the body, with enormous deposits of fat around the pelvis and buttocks, huge thighs, and big legs, while the upper half of the body was relatively unaffected.



—Numbers of babies of various birth weights in various groups of women.

Associated Features

Disturbances of pregnancy seemed to be more common in the obese women, for 11 (10%) of the 109 pregnancies were abnormal (8 from hyperemesis and 3 from toxæmia) against 4 (3·3%) of the 119 control pregnancies (3 from hyperemesis and 1 from toxæmia).

Menstruation is unaffected, for the menses returned normally after parturition in every case, except the one that developed other features of a Cushing's syndrome.

Lactation is also normal, except that in some cases the obesity may be accompanied by an excess of lactation. The 40 women reared 102 children of whom 66 (65%) were fed normally at the breast and the 40 control women reared 117 children, of whom 79 (67·5%) were fed normally; so there is no difference in this respect. Of the 40 obese women, 11 (27·5%) insisted in addition on features indicating an unusually rich supply of milk: in 2 it appeared early in pregnancy, in 2 it continued for long periods after weaning, and in 7 the flow was so abundant that it was virtually continuous, amounting to a lactorrhœa. One woman actually found it difficult to feed her baby owing to the volume of milk produced, and in addition it poured out all day, soaking her clothes and bed, though the flow ceased normally on weaning. Of the control women, 4 (10%) gave a similar history; so, though more frequent, it is certainly not limited to the obese subjects.

Disturbances of carbohydrate metabolism occurred in some of these obese women in later life. Two were diabetic and under treatment for this condition. Glucose-tolerance curves were performed in 26 cases, of which 6 were abnormal and of diabetic type (fasting level above 120 mg. per 100 ml., and levels which rose above 200 mg. and remained above 120 mg. at two hours). These women appear to provide the reservoir from which those suffering from the "large-baby diabetic syndrome" of later life are recruited.

CHARACTERS OF THE BABIES

The total *fœtal mortality* was 11·4% in the obese women and 9·8% in the controls, made up as follows. The obese women had 8 miscarriages in 123 pregnancies (6·5%), and the controls 11 in 132 pregnancies (8·3%). The obese women had 6 deaths from stillbirth or neonatal death (4·8%) against only 2 deaths (1·5%) in the controls; so that the stillbirth and neonatal-death ratio was in excess of that of the controls.

The *birth weights* of the 109 babies born to the obese women and of the 119 babies born to the control women are shown in table III and the histogram in fig. 3 at once reveals that there were considerable differences. In brief the obese women produced a striking excess of large babies, weighing 10 lb. or over, and the excess may in fact be greater than appears, for the figures for large babies in the control group are higher than those obtained elsewhere.[1,17] It has already been stated that the case-histories suggested that there were two modes of variation in relation to the time of onset of the obesity, and the weights of the babies born to the women that on other grounds had been placed in either group are shown in table III and fig. 3. Several points of interest arise. (1) Nearly all the large babies were born to the women who gained weight with each successive pregnancy, and to those who developed their obesity during pregnancy. (2) It is therefore not surprising that the majority of the large babies were born to the women who combined both features—i.e., gained weight during pregnancy and with each pregnancy. In fact, eleven such women produced 8 of the 10 babies weighing 11 lb. or over found in the whole series of 109 babies. (3) All the small babies, weighing 4 lb. or less, were born to those who developed obesity after the confinement, and the majority of these babies were born to the women whose obesity arose in response to one particular pregnancy.

These statements are made with all reserve—the division between the various types was not always easy, and had to be based on the clinical history, and the numbers are not large; but the differences are so striking that they support the validity of the clinical differentiations, and suggest that more than one mechanism may underlie or accompany the obesity.

PERSONAL CHARACTERISTICS OF THE OBESE WOMEN

Initial Weight.—The weight on marriage and the height were known in 36 cases. 17 had weights at the time of marriage above that of the standard for their height[11] with an average excess of 10 lb., and 16 had weights below the standard with an average deficit of 12 lb., the standard and marriage weights being equal in the other 3. Only 20 of the control women knew their marriage weight (the reason for this discrepancy is not clear), of whom 6 were in excess of the standard with an average of 10 lb. and 14 were below with an average deficit of 12 lb. The evidence does not suggest that the women who subsequently became obese were overweight at the time of marriage, but rather that, whereas they were normal, the women who did not gain weight with pregnancy tended to be subnormal in weight at marriage.

Heredity.—The question of a possible hereditary basis for the condition was approached by an endeavour to discover whether the patient's mother had suffered from obesity and the extent to which the patient's sisters were affected.

Mother.—26 obese women were able to give adequate information concerning their mother, of whom 9 (34%) had developed obesity in relation to the birth of their children, while 17 had not. 37 of the control women were able to give information, of whom 7 (18%) had been affected and 30 had had no change in weight. The mothers therefore had suffered from maternal obesity nearly twice as frequently in the obese patients as among the controls.

Sisters.—The obese women had 37 sisters who had given birth to children, of whom 8 (21%) had developed obesity against 29 who had remained unchanged. The control group had 43 parous sisters, of whom 10 (23%) had developed obesity while 33 had not. There was therefore no difference in this respect between the two groups.

Birth Weights of the Subjects.—It has already been shown that the patients in this series produced an unusual number of large babies. If the condition has a hereditary basis one would expect a similar proportion of the subjects to have themselves been unusually large babies. This is the case. There are obvious inaccuracies in attempting to discover the birth weight of people born many years ago, but 20 women were able to quote the figure without hesitation and of these no less than 3 (15%) gave a birth weight of 11 lb. or over. In the control group 15 women were able to give their birth weights; the highest figure was 9 lb., of were 2. There therefore appears to be a difference. Women with maternal obesity a more apt to be born of mothers who have the same condition, but they are also apt have been big babies at birth.

Appetite.—It is clearly desirable to know habits of women suffering from the degree described here, but the subject is difficult to Not only is there the well-known reluctar obese women to disclose their total food inta may well be different in the two phases of and steady maintenance of weight. 9 of the were willing to coöperate were investiga method described by Widdowson and McC were provided with a spring balance † weighi and instructed to weigh in detail all the foo a period of one week, when the results we from food-tables.[16] There was nothing unu protein, fat, and carbohydrate composition and the average daily caloric intakes of the 1267, 1282, 1290, 1307, 1373, 1396, 1440, The two largest figures were from women phase of gain and the remainder were in th phase, and so far as they go the figures sugge intake is certainly greater in the active p intakes that supported a steady but large w small that their accuracy inevitably comes but it has to be said that they are in agreem almost invariable statement made by these they do not deserve to be fat on account o eat. The matter clearly needs further s controlled conditions.

DISCUSSION

It is well known that pregnant women g largely from fluid retention, but this is alm during the confinement and lying-in perio clearly a different process from the one cussion. At the other end of life, the " diabetic" syndrome has attracted much lately.[1,9,12,15,17-19] Briefly, women wh diabetes in later life tend to have given unusually high proportion of large babies previously, and it is also known that these often obese.[10] It is clear that this is one as condition under discussion, and that the featu described represent the beginning of a pro may, many years later, terminate in diabet The agreement covers the obesity, the large raised fœtal-loss rate, and the late deve diabetes mellitus; and the features associat onset of the condition are therefore of considera

It is inevitable that an explanation of this " diabetic syndrome" should be sought in a of anterior-pituitary function. Briefly, th runs thus. The work of F. G. Young[24,25] has the diabetogenic extract and the growth the anterior pituitary are closely related, an effect produced depends on the age of t puppies responding to an injection by growth dogs by the development of diabetes. An anterior-pituitary function could therefore a both the large size of the babies and the diabetes of the mother, and there is also e that it could produce the raised stillbirth-rat it could also cover the increased lactation some of the cases—if this prove to be an inte the syndrome.

Cogent—indeed compelling—though such a tion of these four features may be, there are t why it is difficult to extend it to cover the obe

here that the recent work on the production of
by experimental damage to the hypothalamus
important. It has been amply shown by numerous
[6 7 12-14 20] that a severe grade of obesity rapidly
appropriate damage to the hypothalamus; that
ppens whether the pituitary be left intact or
l; and that obesity does not occur after pituitary
in the presence of an intact hypothalamus. After
n there is an immediate gain in weight, so that
he first 24 hours rats may increase their weight
uch as 15%, followed by a rate of increase which,
still rapid, is not so great; an animal may gain
at ten times the rate of its unoperated litter
doubling its weight in three months or less; and
keys also the weight may be more than doubled,[8]
iod of rapid increase lasting for eight to ten
. This rapid gain of weight is associated with a
us appetite which may be apparent as soon as
mal recovers from the anæsthetic. The animal
ters a static phase in which the weight remains
t at its new high level for many months. It is
that the clinical details of the patients provide
parallel. There is the same sudden start to the
n, with a very rapid initial rate of gain followed
ely by a stage of permanent equilibrium in which
ght remains steady at its new high level. Further,
al gain is of the same order in the experimental
and the patients. As much as 74% of the total
weight of the animals may be due to fat, while
most severe case of obesity recorded here 55% of
ght would be due to fat, the patient having added
o her original weight. While, however, the experi-
obesity is clearly associated with a marked
e of appetite, its importance in the human being
yet determined.

utopsy records of the condition in the human
re available, and any discussion on its mechanism
efore speculative; but the following hypothesis
best to fit the facts in the light of our present
dge. The primary disturbance may well be in the
alamus, which, perhaps as the result of heredity
haps even more as a result of instability during
regnancy and lactation, is apt in these cases to
a disturbance of its normal control of weight. Such
rbance tends in most cases to be permanent; so
effect (to use an analogy) the controls get jammed
open position, and the body rapidly gains weight
t reaches the new level prescribed for it at which
s. In some of the cases the hypothalamic disturb-
produces also an increase in anterior-pituitary
on, which results in the appearance of large babies,
fœtal-loss rate, and an excess lactation, each in
one-third of the cases. The later development of diabetes mellitus may be due to this pituitary hyperfunction or may be merely the result of the prolonged obesity.

SUMMARY

An account is given of the circumstances under which 40 women developed obesity in relation to pregnancy. The maximum weight reached was 125% above that on marriage.

The increase might begin either during pregnancy or immediately after the confinement, and might occur after all pregnancies or only after one particular pregnancy—when the baby was often a boy. In typical cases there was an extremely rapid initial gain of weight, which was followed by a static phase when the weight remained stationary at its new high level for an indefinite period, though occasionally there was a later fall.

Abnormal pregnancy was somewhat more frequent than in the controls, menstruation was unaffected, and lactation was normal, though in some cases there was an excess of milk. In later life some of these women developed abnormalities of carbohydrate metabolism, and 2 were diabetic.

The stillbirth and neonatal mortality was raised, and the women produced an excess of large babies, which were, however, almost entirely born to those women who developed obesity in the course of each pregnancy. Small babies were, by contrast, confined to those women who became fat after confinement from a particular pregnancy. Their mothers had suffered from the same condition more frequently than normal, though their sisters were not specially affected, and they themselves showed a tendency to have been unusually large babies at birth. It is clear that these women provide the reservoir from which patients with the "large-baby diabetic syndrome" are recruited, though not all are so affected.

Though an explanation along the lines of an increased anterior-pituitary function could account for the large babies, the raised fœtal death-rate, excess lactation, and subsequent diabetes, it is not felt that the obesity can be so easily explained. It is therefore suggested that this may be due to a hypothalamic disturbance, which produces an obesity of similar nature to that which follows experimental injury to the hypothalamus, and in a proportion of cases also causes a disturbance of anterior pituitary function, which in the cases concerned, leads to the features of the "large-baby diabetic syndrome."

It is a pleasure to acknowledge my indebtedness to Prof. R. A. McCance, F.R.S., for much helpful and stimulating discussion on the matters raised in this lecture; and to Dr. S. C. Dyke, pathologist to The Royal Hospital, Wolverhampton, and Dr. A. G. Marshall, pathologist to the Guest Hospital, Dudley, for their help with the glucose-tolerance curves.

THE HEALTH OF NURSES IN HOSPITAL *

DONALD COURT
M.D. Birm., M.R.C.P., D.C.H.
READER IN CHILD HEALTH, UNIVERSITY OF DURHAM

AN exact measure of the risk to health in nursing has still to be made in this country. Surveys by the American Hospital Association (1938) suggest that it is considerably greater than in college students and teachers—a reasonable expectation when adolescents and young adults are continuously exposed to disease. Until detailed studies of the health of women employed in different forms of nursing are made we must rely on the findings of particular hospitals. This survey of the nurses' health in an urban hospital, is added to those of Branson (1933), Wright (1944), and Cowen (1947) in the hope that the facts revealed will lead to the more effective care of nurses' health and greater efficiency in the nursing services.

THE HOSPITAL AND NURSING STAFF

The hospital is situated in the Thames Valley 17 miles from London. It was built in 1940 in the familiar hutted pattern of the Emergency Medical Service. The 650 beds were used for military and civilian casualties and increasingly by the surrounding urban population. At the end of 1941 a nurses' training school was established and from 1941 to 1944 it was an associate hospital of the Westminster Medical School.

The trained nurses, with a yearly income of from £220 to £500, were mainly unmarried and lived in lodgings at varying distances from the hospital. The students came from widely differing backgrounds. Of those entering in the period under review, 70% came from Britain, 20% from Eire, and 10% from Europe. 60% had had no more than elementary education. They were resident and received a salary rising from £53 in the first year to £80 on completing their training. The untrained or partly trained group was a mixed one. The "auxiliaries" were women with little or no previous hospital experience, who were non-resident and received £126 per annum with dinner and tea when on duty. The assistants, with a wider age range and often considerable hospital experience, were also non-resident and received £140–185 a year with meals when in hospital.

The age pattern of these four groups on entering the survey is shown in fig. 1. I was responsible for the supervision of their health from 1940 to 1946, and this study covers the three years 1943–45—a period of stability in staffing and the training life of a complete nursing school. The details of the examination type of records have been described in a previous (Court 1943).

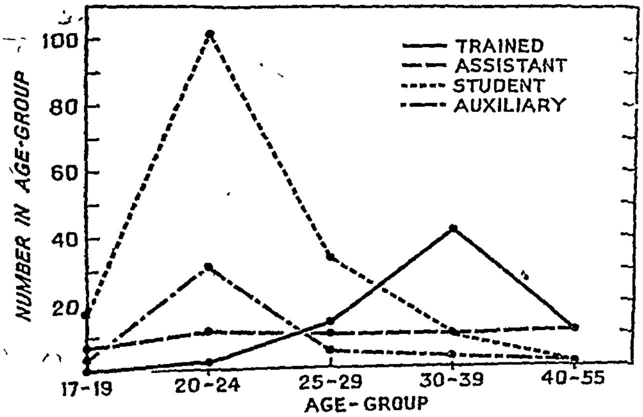

Fig. 1—The age-distribution of the four groups.

Health at the First Examination

A detailed initial history, though restricted by *limitation of the candidate's memory,* is always while. Some of the facts revealed—many of which be considered when selecting nurses—are given in

The dental state was regarded as "good" teeth were present and free from untreated caries, when not more than 4 teeth were missing and untreated caries was present in several, "poor" many teeth were missing, with caries in more 3, and possibly associated gingivitis. Normal vision taken as 6/6 or less on the Snellen scale. A third of refractive errors were uncorrected or inadequa treated when first seen.

TABLE I—PREVIOUS HEALTH AND PRESENT CONDITION AT EXAMINATION (% AFFECTED)

—	Trained	Student	Assistant	
Frequent colds	1	7	9	
Recurrent sore throat ..	6	0	4	
Tonsillectomy	22	32	30	
Rheumatic fever	..	1·7	4	
Severe dysmenorrhœa ..	..	2	2	
Defective vision	27	21	30	
Defective dentition ..	75	49	74	
Varicose veins	20	7	28	8
Hallux valgus	18	4	9	6
Acne vulgaris	2	10	2	14
Vaccination	68	35	28	19
Organic heart-disease ..	..	2	1	1
Innocent cardiac murmurs	6	16	9	18
Number of nurses examined	93	230	80	91

The figures for hallux valgus *do not* fully reveal unsatisfactory state of the feet in many nurses. C and callosities were the rule and the help of orthop surgeon and chiropodist was often required. Acne mild, except in 3 young nurses, but it has infecti possibilities in surgical wards and theatres, and sho not be dismissed as an adolescent inconvenience.

The incidence of organic heart-disease (1–2%) similar to that calculated by Morris and Titmuss for the whole population. The remaining murm were short, systolic in time, and weakened or unchan by exercise. As cardioscopy in these nurses was norm the murmurs were regarded, in Evans's sense of the te as innocent. The average blood-pressure was be 130 systolic and not more than 80 diastolic in all nur under fifty years of age. There were 5 nurses w systolic pressures persistently over 150 and diast pressures of 90 or more, but they were not distre- in any way and were capable of fulfilling their duties

Anæmia.—If we accept 80% or 12 grammes of hæm globin per 100 millilitres as a rough dividing line, were anæmic on entry, an incidence lower than in surveys (Whatley 1942, Wright 1942). No detailed of cell size and hæmoglobin concentration were but an effective response to iron occurred in 15 19 who received ferrous sulphate gr. 18 daily for months.

Relative Immunity to Diphtheria.—33% of the aged 17–19 years, 45% aged 20–29, 55% aged 30- and 70% aged 40–49, were Schick-negative. T positive reactors were immunised using three doses T.A.F. and there were sharp reactions in 10 nurses, 6% those being immunised.

Sickness

MEASUREMENT OF SICKNESS

Though sickness can be more accurately assessed nurses than in the general population, there are difficulties. The average number of days lost the

Annual attack-rate excluding one-day illnesses	0·7	0·8	1·2	1·3

TYPES OF SICKNESS

Respiratory Infection.—Table VI shows that the main component of nursing illness is infection of the respiratory tract. This, including the common cold, nasal sinusitis, tonsillitis, bronchitis, pneumonia, influenza, and acute undifferentiated respiratory disease, was easily first both in the number of working days lost and the proportion of the staff involved. Cowen, studying the same period, Branson (1933), and Rhoads and Afremow (1938) in Chicago found a very similar incidence. Wright's figures for this group of diseases (see table VII) are considerably lower, but it is not clear whether she included all respiratory infections, or whether some are hidden in her large "miscellaneous" group.

Infections of the Skin and Hands.—This group is next in importance, though there is a greater variation in different surveys. It consisted mainly of boils, whitlows, impetigo, and scabies. The incidence of skin sepsis is

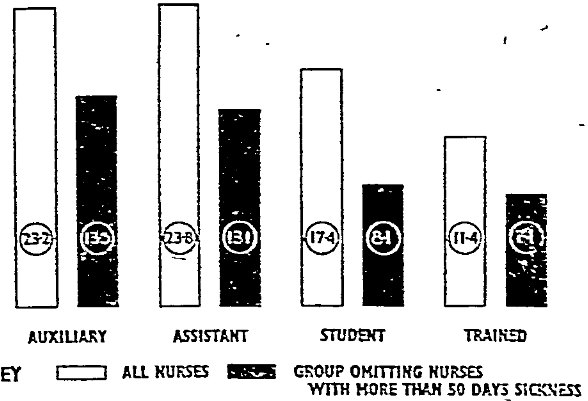

Fig. 2—The average individual sickness in days per year for the whole survey period.

TABLE V—EXTENT OF SICKNESS AMONG NURSES IN FOUR SURVEYS

Author	Type of nurse	Period	No.	All sickness: Annual attack-rate per nurse	All sickness: Annual sickness per nurse (days)	Sickness of less than 100 days: Annual attack-rate per nurse	Sickness of less than 100 days: Annual sickness per nurse (days)

	Assistants Auxiliaries	,,	212	1·8	23·5	1·8	18·4

much greater in Branson's and Wright's surveys than in the present one; in fact Wright points out that her investigation was stimulated by the frequency of whitlows in her own hospital.

Gastro-enteritis includes true dysentery and unclassified diarrhœa and vomiting; there were no large outbreaks, though this group of diseases is endemic among nurses in most large hospitals.

Injury occurred mainly when the nurses were off duty. Four of the accidents were severe and there was one death. The relatively high incidence was probably due to the necessity for many to live at some distance from the hospital and to cycle to and from their work in black-out conditions.

Tuberculosis will be considered separately. Although relatively few nurses were involved, the total loss of working time was very great.

Infectious fevers included infective hepatitis and zoster, as well as the exanthemata, and chiefly affected the younger nurses.

SEASONAL AND DEPARTMENTAL DISTRIBUTION

The highest incidence of sickness was in the first three months of each year, because of the dominating effects of respiratory infection. Though infective illness often appeared to start after periods of duty in the children's ward and in a small "isolation" unit, records were not equal to statistical analysis.

COMPARISON OF SICKNESS WITH OTHER GROUPS

No comparable surveys of women in other have been made in this country. The American given in table VIII suggest that the incidence in nurses is four times greater than in college and twice as great as in women teachers of all

Diehl (1935) compared the sickness-rates of nurses with other college students of the same a year, and found respiratory infections were and superficial pyogenic infections three times, as in the nurses.

Carmalt-Jones (1933) found an annual incidence tuberculosis of 3% in 169 nurses watched for 2 compared with 0·1% in 1125 women of the same in three other colleges not concerned with The surveys by Heimbeck (1936), Scheel (1937), Malmross and Hedvall (1938) in Scandinavia also that the morbidity from tuberculosis is four or times as high in medical students and nurses as in students. Though statistical proof requires surveys of professional women of the same age, it highly probable that there is a greater risk to health nursing than in other professions.

TUBERCULOSIS

The consideration of tuberculosis in relation to nursi requires a definition of tuberculous disease.

Scheel has suggested "a condition of clinical of tuberculous ætiology." While this recognises importance of manifest primary tuberculosis and thema nodosum, he does not include chance radiolog findings in individuals who have had no symptoms illness such as fever or cough. Since pulmonary les destined to give rise to serious disease may remain lat for long periods this definition is unsatisfactory. Prophit Committee in this country have formula more detailed standards (Daniels 1944). These give weight to both the clinical and radiological features the disease and have been used as far as possible in survey. At the same time Daniels, when asse tuberculosis morbidity in nurses, excluded "uncom cated primary focus or complex" and "eryth nodosum with no accompanying evidence of tubercu lesions." But what is an uncomplicated primary comp It is well known that unless radiography of the pri stage is frequent the X-ray signs may be missed. Furt

oux-conversion associated with symptoms, a raised -sedimentation rate, and possibly erythema nodosum, necessitating loss of working time, must surely, heel suggests, be accepted as representing tubercu- isease, whatever the X-ray findings. The subsequent opment of the bronchogenic phase is not conditioned e initial severity of the primary lesion. It seems able to combine these two concepts and with rds and Penman (1945) include "every case which ed any symptom or sign except elevation of the rocyte-sedimentation rate alone or a retrogressing ry complex among the cases of illness."

is has been done in the present survey and only of Mantoux-conversion without clinical or X-ray nce of disease have been excluded.

TUBERCULOUS INFECTION

e fact that more people are reaching adult life out infection by the tubercle bacillus is now recog- l. The first necessity in the continuous study of a p of nurses is to separate the infected from the fected. It is generally accepted that, with rare ptions, the change from a negative to a positive toux reaction shows that infection has taken place. rtunately agreement on a standard test technique yet to be reached. In this survey Old Tuberculin used and fresh solutions made every 14 days. The was taken when necessary to a strength of 1 milli- ime, with a minimum positive standard at 48 hours millimetres or more of œdema and induration, with ounding erythema. If the test reaction was in t or frankly negative the test was repeated with fied protein derivative (P.P.D., 0·00002 and 0·005 . The results in this and other surveys are n in table IX.

VII—COMPARISON OF THE PART PLAYED BY RESPIRATORY AND SKIN INFECTIONS IN DIFFERENT SURVEYS

ior	Type of nurse	Year	Respiratory Tract		Skin	
			Annual attacks of illness (%)	Days lost from sickness each year (%)	Annual attacks of illness (%)	Days lost from sickness each year (%)
son 3)	Trained	1922–26	37	..	23	..
	Student	1927–31	35	..	22	..
ght (4)	Trained Student Auxiliaries	1936–38	28	24	29	25
en 17)	Staff nurses Student	1943–46	42	35	15	11
ent ey	Trained Student Assistant Auxiliary	1943–45	40	30	9	7

he proportion of negative reactors is lowest in the ent survey, probably because many of the students between twenty and thirty years of age and a proportion of the whole group had worked in itals before. Among a group of 125 nurses with no ious hospital experience 21% were Mantoux- ative on first examination, a figure very similar to of the Prophit Survey (Daniels 1944).

hese figures suggest that in Britain now, one girl in y five reaches adult life without a primary infection h tuberculosis. These negative reactors are infected ospital, but at varying speeds, as shown in table X.

aniels suggested that these differences were related the type of hospital, rapid conversion, and a high ree of tuberculin sensitivity developing in those hospitals which admitted "all classes of patient including cases of advanced tuberculosis." The hospital under review belongs to this category yet the conversion-rate was slow. This may be explained by the fact that no negative reactors were allowed to work in the tuberculosis wards, and, recognising the danger of the unsuspected case, all patients with cough or sputum were promptly investigated and where necessary placed in the tuberculosis wards or the isolation unit. That intensity of exposure is not the only factor is shown by the presence in the hospital of a small number of negative reactors, one of them a sister, after three or more years of hospital life. Roberts (1945), working in a large sanatorium, also says that he met with slow conversion of this order in girls working for long period in tuberculosis wards.

TABLE VIII—COMPARISON OF SICKNESS IN NURSES AND OTHER PROFESSIONAL WOMEN

Group	Period	Nurses	Ages	Annual sickness per person in days	
Nurses—					
Trained (Britain)	1943–45	140	21–45	7·1	Excluding illness over 50 days
Student ,,	,,	418	17–30	8·1	
Auxiliaries ,,	,,	212	17–55	13·3	
Trained (U.S.A.)	1937–38	8794	21–35	6·6	
Student ,,	,,	17,364	18–25	8·3	
College students (non-medical) (U.S.A.)	1925–26	1258	17–20	1 8	
Teachers (U.S.A.) ..	1934–35	3270	20–60	3·5	

The clinical features of primary tuberculosis are well known. Of 23 nurses who experienced their first infection during the survey 15 had no symptoms of any kind. Of the remainder 5 had fever, 4 erythema nodosum, 4 pain in the chest, 3 cough, 3 loss in weight, and 1 joint pains. Convincing X-ray films were obtained from only 5 nurses.

TUBERCULOUS DISEASE

Tuberculosis was found in 6 (1·2%) of the 494 candidates at their first examination. The clinical features and subsequent progress are given in an appendix.†

TABLE IX—INITIAL TUBERCULIN REACTIONS IN DIFFERENT SURVEYS

Author	Year	Group	No. tested	Mantoux	
				Positive (%)	Negative (%)
American Student Health Association	1936–37	Students	32,281	30 5	69·5
Amberson and Riggins (U.S.A.)	1936	Nurses	539	57·9	42·3
Hedvall (Sweden)..	1937	Students inc. nurses	3336	81·5	18 5
Holm (Denmark)..	1928	Medical Students	1608	75·0	25 0
Prophit Survey (England) ..	1944	Nurses	3764	80·8	19 2
Present survey ..	1943	Nurses	303	87·2	12·8

Tuberculosis developed during the survey in 18 nurses, with a yearly incidence of 2·6%, 2·1%, and 2·4%. The main categories are shown in table XI, and the individual details in an appendix.†

Some comparison of the incidence and character of the disease in the positive and negative groups must be attempted, though deductions are dangerous without prolonged observation.

Table XII shows the position in the present study and table XIII results in other surveys. The higher incidence of disease in the tuberculin-negative group, accepted by most observers, is readily explained by late primary infection. Of the 7 "negative" cases in this survey, 3 required sanatorium treatment but no serious bronchogenic or hæmatogenous lesions developed within one to two years of the initial illness and there were no deaths. Of the 11 "positive" cases, 7 were latent or detected by regular radiography and 4 were clinically active;. 5 required sanatorium treatment varying from six to eighteen months. There were no deaths, though the disease recurred in 2 cases and in 5 was not considered quiescent until twelve to thirty months later.

---

† Multigraphed copies of this appendix are obtainable on application to THE LANCET Office, 7, Adam Street, London, W.C.2.

TABLE X—MANTOUX-CONVERSION DURING TRAINING (ADAPTED FROM DANIELS 1044)

Country	Author	No. of negative reactors	% initially negative who became positive in		
			1 year	2 years	3 years
U.S.A. ..	Amberson and Riggins (1936)	70	..	..	86
	Israel et al. (1941)	277	86	95	..
New Zealand	North (1911)	104	35	..	..
		61	..	..	64
England ..	Present survey (1945)	11	36	..	..
		20	..	60	..
		8	..	..	87

The condition of the 24 cases at the end of the survey was as follows: 9 had recovered with normal radiographs, 11 were quiescent, and 4 were active; 12 were still nursing, 5 had resigned, 5 were under dispensary observation, and 2 had returned to sanatorium for further treatment. The working days lost by the whole group were over 3000.

Though the numbers involved and the corresponding effect on the staffing needs of the hospital are small, the importance of this disease to the individual nurse is very great indeed. Only half those affected were still nursing at the end of the survey. The final outcome for the others is unknown and a larger series still awaits careful analysis. Andrews (1943), commenting on this culpable ignorance, gave the details of 56 tuberculous nurses whose progress she had followed: 8 were dead, 18 were ill at home or in sanatoria, 12 had resigned from nursing, and 18 were still nursing.

TABLE XI—TYPE OF TUBERCULOUS DISEASE ARISING AFTER ENTRY TO THIS SURVEY

Class	Initial Mantoux reaction		Total
	Positive	Negative	
Clinically active pulmonary	1	..	1
Latent subclinical pulmonary (progressive)	3	..	3
Latent subclinical pulmonary (non-progressive	4	..	4
Pleural effusion only	1	1	2
Primary focus or complex	..	6	6
Extrapulmonary tuberculosis only ..	2	..	2
Total	11	7	18

The relatively mild disease and favourable prognosis for the negative reactor in the present survey is by no means the rule. Heimbeck in the eight years 1928–36 had 10 deaths from tuberculosis in the negative unvaccinated group and no death in the positive group. Daniels (1944), too, found that of the 33 cases following primary infection in hospital 9 developed extensive pulmonary or disseminated lesions and 2 died. Edwards and Penman (1945), like myself, found a less severe type of disease and no mortality. It is clear that the incidence and severity of tuberculosis among n varies considerably. Relating incidence to obserr years, the incidence at the Ullevaal Hospital in (153 per 1000) is eight times greater than the P figure of 19, and the present survey (78 per 1000) mid between. Though the Prophit mortality figure, all negative reactors (0·27 per 1000), is naturally lower the total female rate for England and Wales (0 7 ages 15–19, 1·06 at ages 20–24), this, together with Scandinavian experience, at least dispels the ten illusion that primary tuberculosis is a benign di with a happy ending.

TABLE XII—INCIDENCE OF TUBERCULOUS DISEASE IN CULIN-POSITIVE AND TUBERCULIN-NEGATIVE GROUPS D THE WHOLE PERIOD

Group	Total	Cases	%	Combined years of observation	Annual rate 1000 tion

—The numbers of nurses leaving the hospital and the profession during the survey.

me-absorbing process, have created a relative ge of nurses. Though more women than ever before itering the profession, the estimated shortage ember, 1948, was 33,000. This figure is based on vacancies registered at the appointment offices Ministry of Labour and takes no account of the ion of hospital needs implied by the new health . That this service will call for more nurses is , but the real number required is not clear. The given above are based on the traditional use of e's time and skill—a tradition long immune from l investigation and retaining concepts of function scipline discarded in other professions. Further, ive no idea of how many women entering the ion leave before their training is completed and in ars immediately after qualification. A substantial e of student nurses has long been accepted as an ble element in their training. Even in the r Nightingale School at St. Thomas's Hospital 0% of the candidates completed their training of one year. More recently the serious loss of l staff quite soon after qualification has been ised (King Edward's Hospital Fund 1948).

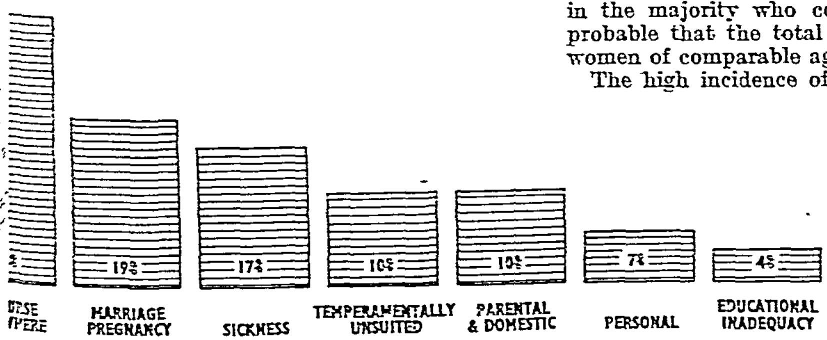

Fig. 4—The reasons for nurses leaving the survey hospital 1943-45.

view of the pressing importance of this problem to taffing of hospitals, it is pertinent to inquire what ickness plays in the problem of wastage.

degree and character of the changes in the nursing of this hospital from 1943 to 1945 are shown in 3 and 4 and tables XV and XVI. Though these s refer to the last three years of the second world vith understaffing, bombing, and domestic upheaval, n valid conclusions can be drawn. The loss of of students during training is very near the 40% l by THE LANCET Commission (1932) and the 43% ll municipal hospitals in 1937–43 (Working Party , which suggests that the factors responsible have nued in peace and war for the past fifteen years.

hen the particular reasons for leaving are examined, gnificant fact is the high place taken by illness— of all leavers and 25% of those who left the profession. this is no freak figure is confirmed by the findings of the Working Party (1947). Though the high figure for the complex of causes labelled resignation in their report limits the value of the remainder, illness was the greatest single cause of wastage.

In this survey the chief offender was emotional instability which accounted for 16 out of the 53 withdrawals because of ill health. The picture was at first sight one of long or recurrent physical illness, but more careful observation revealed the underlying hypochondriasis and psychoneurotic anxiety. The nurses were all cared for by a physician with considerable psychiatric experience. The prominent part played by mental illness is not surprising when we remember that numerous investigations in the past have shown the important part which it can play in the genesis of chronic ill health (Halliday 1935, Walker 1939, Pearson 1938).

TABLE XV—REASONS FOR LEAVING IN THE FOUR NURSING GROUPS

—	To nurse elsewhere	Ill health	Temperamentally unsuited	Educational inadequacy	Marriage or pregnancy	Parental or other domestic claims	Personal
Trained	53·5	3·5	..	..	27·8	11·4	3·8
Student	30 8	15·5	15·5	11·3	14·6	5·8	6·5
Asst.	27·0	20·7	9·5	..	20·6	15·8	6·4
Aux.	27·6	20·0	12·5	..	11·2	13·8	12·0

Figures show percentage of total leaving the hospital 1943-45.

Psychoneurosis however was a minor cause of sickness in the majority who continued nursing, and it seems probable that the total incidence is no higher than in women of comparable age in other professions.

The high incidence of respiratory disease among the leavers (13 of the 53, excluding tuberculosis) is in keeping with its position as the chief cause of sickness among nurses.

Study of the individual illnesses likewise suggests the need for a very careful inquiry into previous respiratory, cardiovascular, and psychoneurotic illnesses at the first interview. It is interesting that none of the 16 cases of psychoneurosis had given any previous personal or family history at their first interview.

Comment

This is essentially a record of sickness—a record of a small group of nurses working in an ill-designed hospital

TABLE XVI—REASONS FOR LEAVING AT DIFFERENT PERIODS (%)

in time of war. Though we know something of their past health, present physique, and relative susceptibility to infection, no assessment of early environment, intelligence, emotional stability, or personal discipline was made. Nor was any study made of such relevant factors as the length of working hours, the pattern of training, or the quality of hospital life in accommodation, feeding and recreation, professional prospects, and, above all, the status and significance of the nurse in the hospital world. Nevertheless, pending wider and more representative investigations, some conclusions can be drawn from the extent and character of the sickness observed, which closely resembles what was found in previous studies. It is highly probable that the health of hospital nurses—notably student, assistant, and auxiliary nurses—is less satisfactory than the health of women in other professions, and this additional illness is mainly due to *Respiratory Infection, Skin Sepsis, Infective Diarrhœa, Infectious Fevers,* and *Tuberculosis.* Further, the proportion of nurses leaving the profession during the early years of training is very high, and illness is a major factor in this persistent wastage. The main problem in preventive medicine today, in hospitals as in the general community, is the control of acute respiratory infection. Yet we know little of the responsible infective agents. The experience of Rhoads and Afremow (1938) that streptococcal sore throat was the greatest single cause of illness among nurses at Cook County Hospital, and created a serious carrier problem in nurses and patients, is shared intermittently by all concerned with the care of people in institutions. Recognition of the importance of the nasal carrier and excretor of hæmolytic streptococci, so clearly proven by Hamburger et al. (1944a), and of dust pollution and dust-borne infection, has brought greater precision into the epidemiology of ward infections with this organism. But the hæmolytic streptococcus is not the whole story. The meticulous studies of army recruits by the Commission on Acute Respiratory Diseases (1947) at Fort Bragg show that non-streptococcal tonsillitis is often twice as common as the streptococcal variety, and that three-quarters of the respiratory infection was most aptly called acute undifferentiated respiratory disease.

After respiratory infections, boils, styes, infected blisters, and whitlows cause the largest number of illnesses and, in the experience of Wright (1944), the greatest loss of time. Staphylococci are the main organisms involved, though in certain outbreaks (Spooner 1941) streptococci may be involved. Though staphylococci are often found in the nurse's nasopharynx, a high skin carrier rate is particularly associated with active or recent staphylococcal lesions.

The control of the common fevers and the problem of endemic infective diarrhœa will not be considered in detail. Active immunisation is effective only against diphtheria and to a lesser extent pertussis, though in the latter case immunity is partial and of short duration.

PREVENTION OF TUBERCULOSIS AND OTHER INFECTIONS

Tuberculosis, though affecting a minority of the staff, was second only to respiratory infection in total loss of working time. Further, the outlook for the individual nurse and the fear which the community has of this disease give it particular significance in the care and recruitment of nurses. While exaggerated respect continues to be paid to diseases such as scarlet fever, it is astonishing to find how ignorant people are, even within hospitals, of the high infectivity of tuberculosis. Geer (1934), by facing this single fact and introducing an extremely detailed anti-infective ritual, reduced the tuberculosis morbidity among his sanatorium nurses from 5·5% during 1928–30 to 1·6% for 1931–34. The logical inference from earlier data in this paper would be that negative reactors excluded from sanatoria, chest hospitals, and the of general hospitals likely to admit unsuspected of open tuberculosis.

In spite of much fundamental ignorance rel the spread of infection, the worth of certain m is well established.

Method of Admitting Patients.—This is the real ning of success or failure. The preliminary all patients must be made by an experienced assisted by seasoned nurses, and cannot be to newly qualified and inexperienced substitutes. doctor must have the time to inquire into past illnesses and recent contact with infection. Patients obvious upper-respiratory infections, otorrhœa, or other pyogenic dermatitis should not be admitted general wards, but to effective isolation rooms. tonsillitis, whether or not it is accompanied by a and so elevated to the rank of scarlet fever, is be to an isolation hospital or unit.

Attitude of the Nursing Staff.—Once the patient the ward the instructed intelligence of the nursing is the most important factor in controlling With the present shortage of nurses an elaborate of masks and gowns often becomes a façade be which the safer and more important measures neglected. The nurse requires much more imaginative teaching about the nature of infection its danger to herself and her patients than she rece in many hospitals. She should be encouraged to rep early infections in herself without fear of censure. T comment of Bevington (1943) on this point is signific

> “The belief was general in all the hospitals I visited th nurse could not go off duty simply on account of a however heavy it might be. In the course of this inq I interviewed nurses on duty suffering from such heavy c as would have entailed their being sent home from modern office if only to safeguard the rest of the staff.”

Ward Techniques.—The control of ward infe depends not only on the quality but also on the of nurses. Understaffing means hurried nursing and natural omission of preventive measures. Preo with the design of wards and the mechanical of dust have tended to displace the simpler t which can still be carried out in old and uns buildings. Careful washing of the hands between is still the most important single measure, and basins should be so placed in wards that this Dry sweeping of floors should be forbidden and by sweeping with damp sawdust or vacuum A thermometer should be provided for each p and kept in 1 in 60 carbolic or some other disinfectant.

Devenish and Miles (1939) found that ‘Celloph in suitable thickness was impermeable to staphyloc and recommended a mask consisting of a $6^{3}/_{4} \times 8^{1}/$ sheet of cellophane (no. 600) sewn into a 7 × pocket made in the middle of the upper border of a of double folded muslin 36 × 15 in. and sterilised in Masks should be reserved for special cases; they sho be worn both by the nurse and the patient; and th should not be worn for more than two hours at a On removal they should be placed immediately disinfectant and not left lying about for subsequent us

Bed linen forms an immense reservoir of bact which are generously dispersed when beds are ma This dispersion can be much reduced by the use o little technical white oil in the final stages of laundri

Finally the proper care and cleansing of crockery ne more thought than it generally receives. The infe patient is given special crockery which is boiled a use, but the general sharing of other crockery, wh cracks are known to be a secure nidus for bacteria

accepted. Attention to these details is within capacity of most hospitals, and can diminish infection both in staff and patients.

SUPERVISION OF NURSES' HEALTH

e *initial examination* should be carried out by an ienced physician, responsible for the continuing vision of the nurses' health and for the keeping of ds. Table XVII shows the differing pattern of care e large voluntary and municipal hospitals in different of Great Britain in 1945. When reviewing the health, special attention must be paid to family or nal mental illnesses, recurrent respiratory infection, tuberculosis.

e examination should include a postero-anterior of the chest, complete Mantoux and Schick testing, globin estimation, and careful examination of the teeth, nose and throat, feet, and urine. In view e unsatisfactory state of the feet in many nurses, often necessary for them to be seen early by an pædic surgeon and in some cases by a chiropodist. tment, combined with careful advice on shoes and ise, would go far to reduce the foot strain experienced any, especially during the first nursing year. Dental sment would be helped by the establishment of pted categories of dental adequacy by the British al Association. Where available, cardioscopy should rried out in all cases with any cardiac abnormality though the murmur is considered innocent.

rther Routine Examinations.—A second examination a three months' probationary period is desirable re final acceptance. The extent of this would rally be determined by the results of the first inter- . Apart from checking any physical defects it ld be possible in the light of ward and training-ol reports to reach a more reliable judgment of entrant's character and temperament. After this, ual re-examination probably suffices, with the ition of special scrutiny after periods on night duty, uberculosis wards, and on returning from sick-leave. hest films and hæmoglobin estimations should also taken annually, though the first should be repeated within three months of being on the tuberculosis wards and the second after a substantial period of night duty. Tuberculin-negative nurses should be retested every three months, and further chest films should be taken on conversion from negative to positive.

Immunisation.—Schick testing is desirable, followed by full immunisation in positive reactors and a single stimulating dose in young negative reactors. Vaccination and revaccination against smallpox and the enteric fevers should be encouraged.

Prevention and Control of Tuberculosis.—In view of the special danger of this disease, the young student and assistant should be assured that special protective measures will be taken. All should be tuberculin-tested within two months of entry into the hospital or training school. Freshly made Old Tuberculin, from 0·01 to 1 mg., or P.P.D. 0·00002 to 0·001 mg. should be used and 10 mm. or more of swelling at 72 hours taken as a positive reaction. If tuberculin-negative, the nurse should be retested every three months until positive.

Radiography of the chest will be undertaken on entry, and then annually unless Mantoux-conversion or suggestive symptoms occur before that time. Mantoux-negative nurses should be encouraged to report promptly any cough, fever, and loss of appetite or weight.

Nurses who are Mantoux-negative should not work on tuberculosis wards unless strict measures to prevent massive infection are enforced. The striking if limited value of B.C.G. vaccination shown by the Scandinavian surveys suggest that this procedure could be a useful addition to the measures already described.

Cases of known tuberculosis should not be admitted to general wards and sputum from any patient should be promptly examined for tubercle bacilli.

Treatment on "Conversion."—No general agreement on this point has yet been reached, but personal experience, together with discussions with many friends working in the tuberculosis service, suggests the advisability of the following measures.

Nurses without symptoms or X-ray evidence of the primary complex may remain on full duty. They should be encouraged to retire early to bed and to avoid strenuous exercise for the next month and be seen at the end of three months. If still normal, they should have further X-ray films at the end of the year or earlier if symptoms of any kind develop.

Those without symptoms but with a raised erythrocyte-sedimentation rate and with a visible primary complex in the lungs, should remain in bed in hospital until the E.S.R. is normal. If the X-ray film then shows no progression they can take up part-time duties, with a return to full duty in three months.

Nurses who are ill and show radiographic signs of extensive or progressive primary tuberculosis should be treated in a sanatorium for as long as necessary.

Positive reactors require radiography on entry and annually thereafter. If they lose weight or develop anæmia, cough, or indigestion special investigation will of course be needed.

CARE OF THE SICK NURSE

Any nurse must be able to report sick at any time without fear of rebuke. In particular she must learn to understand the potential danger to herself and her patients of such minor illnesses as the mild cold and the septic blister. The reluctance of trained staff to pay attention to such matters, and of administrators to release—for so slight a cause—nurses sorely needed on the ward, must be overcome. The nurse, too, should have direct access to the responsible physician without the intermediate permission of matron or home sister.

The sick-ward accommodation should be generous and attractive so that non-resident as well as student nurses will be encouraged to accept treatment in hospital. To assist this further, a free choice of the senior medical staff should be allowed. Table XVII is instructive here, especially in view of the profession's devotion to this principle in relation to the general public. Even with generous convalescence, loss of working time is almost certainly lower in those treated in hospital.

HEALTH EDUCATION

Explanation is the first essential of coöperation. Each group of students and assistants should be told the nature of, and reasons for, the careful supervision of their health during their stay in hospital. If stress is laid on the relative ease with which departures from normal can be corrected in the early stages, a sense of security and a desire to coöperate prevails from the beginning. Any abnormality, uncertain shadows in the chest film, lowered hæmoglobin, loss in weight, a high sickness-rate, or the like, should be discussed in private with the nurse concerned. Nurses are particularly apprehensive about tuberculosis, and find it very difficult to understand the significance of Mantoux-testing. Nurses should be encouraged to take an intelligent interest in the sickness records of their own hospitals and a pride in a high standard of health. Simple advice should be given on feeding, sleep, and the full use of leisure; and it is here that welfare supervisors should prove their worth. At the same time no physician concerned with the nurses' health can afford to ignore the feeding and recreational facilities in his own hospital. In the hospital of which I am writing, committees to watch over these two activities were established in 1942 and have worked actively ever since.

WASTAGE AND ITS PREVENTION

Wastage has been considered in detail for two reasons. First, ill health plays a major and previously unsuspected part in the process. Secondly, such analysis reveals something of the relation between health and environment in the genesis of this complex problem. The health and well-being of nurses in hospital is a function of many circumstances and activities between which rigid lines cannot be drawn. Time lost through illness is costly to the hospital, the nurse, and the patient. The cost to the hospital can be measured in financial terms; the cost to the nurse is often personal disappointment and professional failure; while the cost to the patient may be a limited quantity and a poorer quality of nursing care.

With our clearer understanding of the nature of d and our more effective remedies for infective il should now be possible, without further knowledge, reduce substantially the present level of sickness hospital nurses.

Summary

The health of 300 nurses in a general hospital studied during the three years 1943–45. The extent sickness was assessed by the number completely from sickness, the average amount of sickness per and the proportion of each group with " sickness " (more than 50 days in the year), and figures for the three main groups were:

	Trained nurses	*Student nurses*	*Ass and auxi*
Free from sickness	11% ..	38% ..	16%
Average sickness per head per annum..	7 days ..	8 days ..	13
Sick more than 50 days per annum	5% ..	10% ..	12%

It is very probable that the health of hospital is less satisfactory than the health of women in professions and that this excessive illness is due to respiratory infection, skin sepsis, diarrhœa, infectious fevers, and tuberculosis.

Of the 300 nurses, 18 (6%) developed tub. during the survey, with the loss of 3000 working There were no deaths from this disease during the years.

Ill health was found to play a large and unsuspec part in wastage; 17% of those leaving the hospital 25% of those leaving the profession (at least temp did so for this reason.

In the light of this and other surveys the concerned in the reasonable care of the hospital nu health are considered and a number of practices propo which could be carried out readily in most hospitals.

It is very pleasant to remember all who helped so genero with records and administration, comment, and encou ment: especially Mrs. Lang and Miss Herrington, the ma and assistant matron; Mr. G. Stephen, the medical dire Dr. Barham Carter, Dr. Gordon Signy and Prof. R. C. Bro and Mr. H. Campbell, *the statistician.*

ROLOGICAL EFFECTS OF OXYGEN IN CHRONIC COR PULMONALE

C. E. DAVIES
, B.M. Oxfd. M.R.C.P.
EARCH ASSISTANT IN
INICAL MEDICINE

J. MACKINNON
M.B. Sheff.
JUNIOR
REGISTRAR

ERSITY DEPARTMENT OF MEDICINE, THE ROYAL HOSPITAL,
SHEFFIELD

YGEN, at pressures up to one atmosphere, is generally ded as a safe and important therapeutic agent in estive heart-failure due to chronic disease of the lungs mic cor pulmonale). The deficient oxygen saturation e arterial blood, which is a prominent feature of this ition, is in most cases rapidly alleviated, with corre- ding clinical improvement. Relief of anoxia in this is thought to assist myocardial function, and should le the oxygen requirements of the tissues to be met a cardiac output below the high level found in eated cases of this disease (Howarth et al. 1947).

cent experience in this department suggests that en therapy may produce changes in the intracranial lation of patients with chronic cor pulmonale, and untoward effects sometimes follow.

CASE-RECORDS

se 1.—A man, aged 48, was admitted to hospital on 26, 1948, under the care of Prof. C. H. Stuart-Harris, ongestive heart-failure with deep cyanosis secondary to nic bronchitis and emphysema. His alkali reserve was l. of CO_2 %. When oxygen was given either by B.L.B. or by oxygen tent his arms developed uncontrollable lonic movements, his head and neck sweated profusely, he complained of a fullness in the head. When oxygen was drawn these symptoms disappeared. Signs of tetany l not be elicited.

se 2.—A man, aged 49, was first admitted to hospital r the care of Dr. A. R. Kelsall in February, 1948, with a nosis of congestive heart-failure due to chronic bronchitis emphysema. He had polycythæmia (hæmatocrit 67%), his vital capacity was 1·7 litres. Venesection, rest in bed, mercurial diuretics caused rapid improvement, and the nt was discharged relatively well.

hen readmitted on Nov. 12, 1948, he had more severe estive heart-failure, with very deep cyanosis and moderate ma. Oxygen was given intermittently through a B.L.B. on the day after his admission without ill effect. Next the patient took breakfast normally and spoke sensibly. r breakfast he was given oxygen by B.L.B. mask at t 6 litres a minute. Two hours later he was found nscious by the ward sister and could not be roused. as in deep coma, but his colour was pink in spite of very low respiration; the oxygen mask was still in place. e was a very heavy sweat on his head and neck, and he was ating profusely. His blood-pressure was 115/75 mm.

There were no localising signs in the nervous system. tar responses were flexor. The alkali reserve was ol. of CO_2 %. Because of his shallow breathing the patient given a mixutre of oxygen (90%) and carbon dioxide o) for a short time; this increased the rate and depth spiration and raised his blood-pressure to 170/120 mm. Hg. patient remained unconscious and died two hours later.

ecropsy. (By Dr. J. L. Edwards; 24 hours after death.) rain: weight 1450 g. Deeply congested and slightly matous; a small subarachnoid hæmorrhage, not exceeding l., over the upper surface of the right frontal lobe. On ed-eye examination, larger cerebral vessels showed no eroma or aneurysm; no evidence of embolus or thrombosis. tologically, small vessels and capillaries engorged: small unt of blood in subarachnoid space and in some Virchow- bin spaces; no evidence of fat-embolism.

ungs: small bilateral pleural effusions, slight emphysema. rulent

Comment.—Because of the recent experience with case 1, it was thought that the onset of coma in case 2 might be due to oxygen intoxication. In retrospect it seems that the administration of carbon dioxide was the worst treatment possible for the patient, and may have contributed to his death; but this was not appreciated at the time.

We have not found any published descriptions of the post-mortem appearances of the brain in oxygen poisoning, but the clinical and pathological findings in case 2 bear a striking resemblance to those in cases reported by Hunter (1949) as "anæsthetic encephalopathy."

OBSERVATIONS ON PATIENTS WITH AND WITHOUT COR PULMONALE

The neurological manifestations in cases 1 and 2 suggested that oxygen, as normally given for therapeutic purposes, might produce changes in the cerebral circulation in patients with chronic cor pulmonale. The effect of oxygen on the pressure of the cerebrospinal fluid (C.S.F.) in 4 such patients (cases 3–6) was therefore compared with that in patients with other diseases (cases 7–11).

Methods.—A lumbar-puncture needle of moderate gauge was introduced into the spinal theca between L3 and L4 or between L4 and L5, with the patient lying on the left side at an angle of 30° to the horizontal; the needle was connected to a special manometer 2·5 mm. in diameter and 500 mm. long, care being taken to avoid loss of C.S.F. Gases were administered to the patient by B.L.B. mask or by anæsthetic mask with a soda-lime reabsorber. All observations were made when the patients were relaxed.

A. Cases of Cor Pulmonale

Case 3.—A man, aged 56, with a history of dyspnœa, cough, and sputum since being gassed in the 1914–18 war. He had been disabled by dyspnœa for a year and œdematous for eight weeks. He had recently recovered from a right hemiplegia when the observations were made.

On examination he was deeply cyanosed; venous pressure increased and slight œdema. Chest emphysematous with widespread bronchospasm and basal râles. Pulse-rate 100 per min., regular: blood-pressure 180/80 mm. Hg.

Investigations.—Radiography showed cardiac enlarger and congested pulmonary vessels. Electrocardio showed right ventricular hypertrophy. Vital 1·3 litres; alkali reserve 75 vol. of CO_2 %; arte unsaturation 10 vol. %; hæmatocrit 65%.

Case 4.—A man, aged 55, with a history cough and sputum, two years' dyspnœ swelling of the legs: no angina.

On examination he was deeply venous pressure and œdema. He chest with gross scoliosis, and cl poor chest expansion. Basal r min., with occasional extra mm. Hg (falling to 160/80

Investigations.—Radi and partial long-stan cardiography show rotation of the b 77 vol. of CO hæmatocrit

rise in pressure, and indicated that oxygen was the factor responsible.

(2) As an extension of this last experiment, and to discover whether the phenomenon was confined to pure oxygen, a further observation was made. Air was given to a patient (case 5) with chronic cor pulmonale through a B.L.B. mask at 10 litres a minute; the intrathecal pressure fell and remained below the resting level. Without the mask being moved, a mixture of 50% oxygen and 50% nitrogen, at the same rate of flow, was substituted for air;
arked rise in pressure took place as in former
ions. While the pressure was still rising, air was
re given, and the pressure fell to the resting
. 4).

DISCUSSION

1 and 2 indicate a possible harmful effect of
n cor pulmonale, and the experimental findings
that one such effect is a sharp rise in C.S.F.

We have not demonstrated a similar increase
hecal pressure in the few controls yet examined,
the 4 cases of cor pulmonale (cases 3–6) exhibited
in C.S.F. pressure within a few minutes after
dministration had started. Our observations are
it inadequate to determine whether this effect of
s related to any particular stage of the process
ilmonale, but a raised venous pressure does not
o be essential, because case 3 showed the same
when all evidence of systemic congestion had
ared.

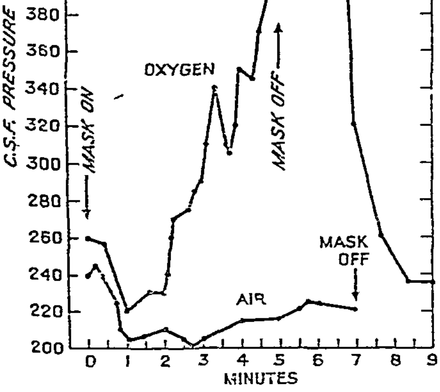

Fig. 3—Comparison of effects of giving oxygen through a tube (see fig. 2), and of giving air in the same way, at 10 litres a minute in cor pulmonale (case 3).

Similar high C.S.F. pressures were recorded by Harrison (1934) in various forms of congestive heart-failure.

It appears unquestionable that the changes observed in the intrathecal pressure reflect similar changes in intracranial pressure. So far as the immediate mechanism is concerned, the rapidity of the fluctuations in pressure suggests an effect on the calibre of the cerebral vessels and accompanying changes in blood-flow. The cerebral vessels are known to dilate when carbon dioxide is given to patients undergoing cerebral operations, and in animals whose pial vessels have been exposed (Cobb and Fremont-Smith 1931, Lennox and Gibbs 1932). We have obtained a sharp increase in the intrathecal pressure by giving carbon dioxide to some of the controls used in connexion with observations on the effect of oxygen. An increase in intrathecal pressure following the giving of oxygen does not, however, seem to have been recorded before.

The changes in intrathecal pressure in cor pulmonale after the giving of oxygen are possibly linked with changes in the metabolism of carbon dioxide. The theory that oxygen intoxication is due to accumulation of carbon dioxide in the body, because of interference with the transport of carbon dioxide by hæmoglobin (Gesell 1923), may explain our findings. Patients with emphysema, especially those with chronic cor pulmonale, are known to retain carbon dioxide, as shown by the high alkali reserve, and a further increase in the carbon dioxide in the tissues might produce toxic symptoms. Work is now in progress in an attempt to confirm or refute this hypothesis. Meanwhile, it is considered that the experiences recorded here should lead to caution in giving oxygen to patients with chronic cor pulmonale.

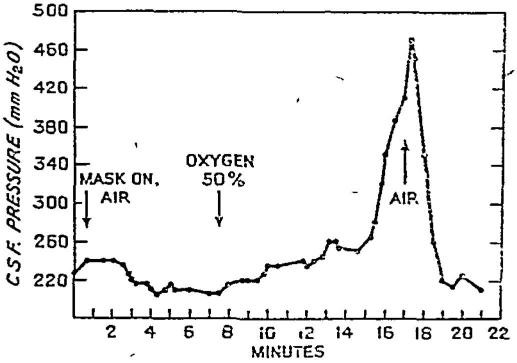

Fig. 4—Comparison of effects of giving oxygen and of giving air at 10 litres a minute through B.L.B. mask in cor pulmonale (case 5).

SUMMARY

Two cases of chronic cor pulmonale are reported in which adverse effects followed the giving of oxygen. In case 1 oxygen was the probable cause of myoclonic arm movements; in case 2 it probably caused coma and may have contributed to death.

Experiments showed that oxygen given in concentrations of 50–100% to patients with chronic cor pulmonale causes a sudden increase in C.S.F. pressure. Such an increase was not observed in controls.

Our thanks are due to Prof. C. H. Stuart-Harris for his assistance and advice and for facilities for the work; Dr. A. R. Kelsall for permission to publish case 2; Dr. J. L. Edwards for the necropsy findings; and Dr. A. Jordan for biochemical results.

spasm. Pulse-rate 96 per min., regular; blood-pressure 130/70 mm. Hg.

Investigations.—Radiography showed chronic fibro-phthisis, and enlargement of the pulmonary conus and heart. Electrocardiography showed right ventricular strain. Vital capacity 1·1 litres; alkali reserve 77 vol. of CO_2 %; arterial oxygen unsaturation 5 vol. %; hæmatocrit 40%.

B. Controls

Case 7.—A married woman, aged 48, with mitral stenosis, auricular fibrillation, venous congestion, and œdema, but no cyanosis.

Case 8.—A man, aged 48, with gastric carcinoma and peritoneal metastases and ascites, but no cyanosis or evidence of congestive heart-failure.

Case 9.—A single woman, aged 74, with iron-deficiency anæmia. Her Hb was 20% (Haldane), her venous pressure was not raised, and she had no œdema.

Case 10.—A single woman, aged 35, with chronic bronchitis, asthma, and slight emphysema, but no cyanosis. Alkali reserve 60 vol. of CO_2 %.

Case 11.—A man, aged 46, with chronic duodenal ulcer no cyanosis.

RESULTS

of Breathing Pure Oxygen in Cor Pulmonale

n initial investigation, oxygen was given at minute to case 3 through anæsthetic apparatus with a carbon-dioxide reabsorber in the circuit open expiratory valve. There was a very rapid C.S.F. pressure, starting within 30 seconds and a height $2^1/_2$ times the resting level. The removed after about 4 minutes, but the tinued to rise for a further minute; abruptly to the original level (fig. 1 and table I). was sweating over the head and neck. The was repeated in this patient ten times on four similar results.

Table I shows that a rise in C.S.F. pressure oxygen administration in the 3 other chronic cor pulmonale (cases 4–6). In all these resting C.S.F. pressure was high. The relative in pressure after oxygen had been given varied somewhat from patient to patient, and in case 6 was trivial. No attempt was made to find the highest C.S.F. pressure attainable or the duration of the response.

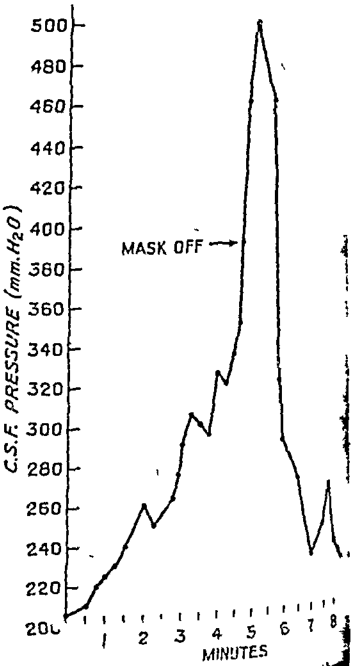

Fig. 1—Effect of breathing pure oxygen, thr anæsthetic apparatus at 6 litres a minute w CO_2 reabsorber in the circuit and expir valve open, in cor pulmonale (case 3).

Control Observations

The five patients who were not suffering from chronic cor pulmonale and were not cyanosed (cases 7–11) were studied in the same way. Oxygen breathing for up to 30 minutes caused no rise in intrathecal pressure, and in most cases was by a fall (table II).

nt moved.

Further Observations

From these simple observations it appeared breathing oxygen caused a significant rise in c. pressure in patients with chronic cor pulmonale, but in the other patients examined. Further observati were made to exclude the possibility that the change pressure were due to the discomfort of breathing mask, or to accumulation of carbon dioxide within apparatus used for giving gas.

(1) To eliminate the discomfort of the mask harness, and to prevent the accumulation of car dioxide within the apparatus, a simple anæsthetic m with a large anterior opening was held on to the patien face by an assistant. Gases were given through a tu passed through the opening in front of the mask (fig. and were delivered in large volumes to ensure that expired carbon dioxide should be driven out of the sp between mask and face. In fig. 3 the effect of oxyg on the intrathecal pressure of a patient with chronic pulmonale is contrasted with the effect of air given the same way and at the same rate. Oxygen caused same rise in pressure as that observed after it had given through a B.L.B. mask or an anæsthetic mac whereas air caused the pressure to fall. This seemed exclude any mechanical factor as a cause of the ot

ıd received A.P. for five months in another hospital. ·ver was intermittent, with an evening maximum of F; sputum was positive, and E.S.R. 100 mm. in 1 hour. graphy revealed thickening of the right parietal pleura orizontal fissure, and a productive lesion in the right zone. Laryngoscopy revealed tuberculosis.

ptomycin therapy was started on Dec. 15, 1948, and ued until 60 g. had been given by Feb. 11, 1949. The t's temperature became normal on Dec. 20, 1948, and arseness and pain disappeared on Feb. 16, 1949, when oscopy revealed complete healing. She is still in the rium, with evening rise of temperature to 100°F; n culturally positive, E.S.R. 66 mm. in 1 hour. Radio- ly there is appreciable reduction in the extent and y of the pulmonary lesions. The patient's weight sed by 15 lb. Period of observation 11 months.

e 3 (IIIC).—A man, aged 25, was admitted on May 19, with twelve months' history of cough and fever. He ceived 22 inductions of A.P. in another hospital. His rature was intermittent, with an evening maximum of F; his sputum was positive, and his E.S.R. 28 mm. in r. Radiography showed an exudative lesion with tion in the right upper and mid lobes, with involvement left perihilar zone. The patient was also diabetic. On isin and insulin the temperature settled to 99·8°F, the n became negative, and the urine became sugar-free.

ptomycin was started on Dec. 19, 1948, because of per- pyrexia, and continued until 40 g. had been given by 27, 1949. On Dec. 25, 1948, the temperature became l. He was discharged on Feb. 25, 1949, his temperature remained normal since Dec. 25, 1948. His sputum egative, his E.S.R. 7 mm. in 1 hour, and radiologically sions in both lung fields had resolved and no cavity pparent. Period of observation 17 months.

e 4 (IIIC).—A woman, aged 30, was admitted on Dec. 15, with a month's history of fever, rigors, cough, and y. Her temperature was remittent, with an evening num of 102°F, her sputum was positive, and her E.S.R. 12 mm. in 1 hour. Radiography revealed a productive in the left upper and mid zones. The patient refused

ptomycin therapy was started on Dec. 24, 1948, and ued until 54 g. had been given by Feb. 28, 1949. The it was discharged at her request on March 3. Her rature had been normal since Jan. 2, her sputum had legative since the end of January, her E.S.R. was 74 mm. our, and radiologically there was an appreciable reduction density of the lesion in the left upper zone. Period of vation 10 months.

se 5 (IIIC).—A woman, aged 25, was admitted on April 28, with eight months' history of irregular fever and chills. emperature was intermittent, with an evening maximum 1°F, her sputum was positive, her E.S.R. was 105 mm. hour, and radiography showed an exudative lesion in ft subclavicular zone with evidence of tissue breakdown. vas treated by A.P. from May 3, 1948, to July 31, 1948. ondition did not improve, and radiography on Aug. 9, showed a spread of tuberculosis to the right subclavicular

eptomycin therapy was begun on Sept. 13, 1948, because pneumothorax developed that day. By Oct. 14, 1948, had been given, and from that day the patient's tem- ure remained normal. She was discharged on May 14, Her sputum had been negative since Jan. 26, and her was 100 mm. in 1 hour. Radiography showed resolution e focus on the right side and encystment of the residual on on the left side. The patient had put on 24½ lb. in ıt. Period of observation 12½ months.

se 6 (IIIC).—A man, aged 24, had been admitted four weeks' history of cough and fever. He had 6 A.P. inductions on the right side elsewhere. On ssion his temperature was intermittent, with an evening mum of 101·2°F, his sputum was positive, his E.S.R. 98 mm. in 1 hour, and radiography showed collapse of pper and mid right lobes, slight collapse of the right lower and an exudative lesion in the right lung and in the left r lobe.

reptomycin was given on Sept. 11, 1948, because A.P. outside had made his condition worse and his general ition was bad. By Jan. 12, 1949, 80 g. had been given. patient's temperature came down to an evening maximum of 99°F on Sept. 15, 1948, and his E.S.R. came down to 64 mm. on Jan. 5, 1949. He gained 31 lb. in weight, but his sputum remained positive. On Jan. 17, 1949, A.P. was begun, because he was now in a suitable condition for it. On Feb. 1, 1949, he got benign tertian malaria, which was soon subdued. On Feb. 16 he had a profuse hæmoptysis, which was soon controlled, but radiography showed recent reinfection of the left mid zone and extensive tissue breakdown, with large cavities, in the right upper lobe. The patient's temperature rose to 101°F. Streptomycin was given again on Feb. 21, and continued until 108 g. had been given by March 21, when his temperature came down to 99·5°F. The patient was discharged on July 21. Period of observation 10 months.

Case 7 (IIIC).—A man, aged 48, was admitted on Sept. 30, 1948, with two months' history of cough and pain in the chest. His temperature was remittent, with an evening maximum of 101·4°F, his sputum was positive, his E.S.R. was 96 mm. in 1 hour, and radiography showed an exudative lesion involving practically the whole of both lung fields, lobular in distribution. A.P. was contra-indicated.

Streptomycin therapy was started on Oct. 5, 1948, and continued until 42 g. had been given by Nov. 19, 1948. The patient was discharged on April 29, 1949, and his temperature had been normal since the very first day of streptomycin therapy. He had gained 18½ lb. in weight. But his sputum was still positive and E.S.R. at the same level. Radiologically there was appreciable resolution on the right and early fibrotic changes on the left. Period of observation 7 months.

Case 8 (IIIC).—A police constable, aged 30, was admitted on Nov. 9, 1948, with three months' history of cough, fever, and pain in the chest. He had been treated for pulmonary tuberculosis in 1946 in another sanatorium, had received there A.P. and gold treatment, and had been discharged after six months as fit for duty. On admission his temperature was intermittent, with an evening maximum of 101·8°F, his sputum was positive, his E.S.R. was 114 in 1 hour, and radiography showed an exudative lesion in the upper half of either field.

Streptomycin therapy was begun on Dec. 21, 1948. Up to Jan. 15, 1949, the patient received 1 g. daily, making a total of 26 g. His response being unsatisfactory, his temperature going up to 103°F, the dose was doubled to 2 g. a day up to Feb. 1, making a grand total of 60 g. His temperature did not abate, and radiography showed an increase in the epituberculer exudation and recent spread to both bases. His sputum continued positive, and his E.S.R. rose to 130 mm. in 1 hour, though he gained 7½ lb. in weight. He was discharged on May 30. Period of observation 6½ months.

Case 9 (IIIC).—A man, aged 54, was admitted on Feb. 13, 1948, with a history of productive cough, fever, and debility of indefinite duration. He was acutely ill and orthopnœic. His temperature was remittent, with an evening maximum of 100°F, his sputum was positive, and his E.S.R. was 142 mm. in 1 hour. His liver was enlarged, and his urine was loaded with albumin. Radiography showed a productive lesion with cavitation in the left upper and both mid zones. A.P. was out of question.

Streptomycin therapy was begun on March 23, 1948, and continued until 18 g. had been given by April 10, 1948. The patient left on May 12, 1948, because his dyspnœa had completely disappeared, his temperature had been normal since April 5, 1948, his weight had increased by 14 lb., and he thought he could look after himself. On his discharge his sputum was positive, radiography showed a recent spread of tuberculosis to both lower lobes, but his E.S.R. had fallen to 94 mm. in 1 hour. He maintained his improvement for two months, but then migrated into Hyderabad State, where he died during the second week of August.

RESULTS IN GROUPS II–VI

The results obtained in the 20 cases in these groups are summarised in tables II and III, which show that, out of 20 cases, response in 13 was favourable, in 4 doubtful, and in 3 unfavourable. Out of 7 in the doubtful and unfavourable category 5 came from groups II and III. Sex seems to have shown no predilection, but ages between 14–25 years reflected better results.

Illustrative Case-records

Case 10 (group II).—A woman, aged 35, was admitted on March, 1948, with four weeks' history of cough, fever, and

GOVERNMENT WELLESLEY TUBERCULOSIS SANATORIUM, BELLARY, SOUTH INDIA

IN India the number of sanatoria is far from being commensurate with the requirements of the population, and general hospitals are averse to admitting tuberculous patients for whom they cannot provide effective treatment. If only the fever of these patients could be controlled, a great step forward would have been taken, for then those who became fit for surgical intervention could be selectively tackled in the sanatoria. Any therapy, therefore, which improved their general condition would be especially welcome in India. If toxæmia and fever can be controlled, the patient's morale rises, and he may then allow the doctor the surgical approach to his body which otherwise he will refuse point-blank.

We report here on the potentialities and limitations of streptomycin as they appear from an inquiry conducted in the Government Wellesley Sanatorium. We set out to answer the following questions:

(1) In what types of pulmonary tuberculosis can streptomycin be used with advantage?

(2) What is the optimum dose of streptomycin, and at what intervals must it be administered?

(3) Is its beneficial effect temporary or permanent?

(4) What are its untoward effects, and how can they be prevented or treated?

(5) Will streptomycin work better when given concurrently with other drugs?

(6) Can streptomycin therapy take the place of present methods of treatment?

(7) What is the smallest quantity of streptomycin required to tide the patient over and make him turn the corner when gravely ill, so that routine surgical treatment may be adopted?

METHOD

Streptomycin hydrochloride (Squibb) and streptomycin sulphate (Pfizer) were used. The sulphate caused less pain and therefore was preferred. Streptomycin 0·5 g. in 2 ml. of distilled water was given intramuscularly morning and evening. For intrapleural injections 100 mg. in 10 ml. of distilled water was given, once a day.

CLASSIFICATION OF TUBERCULOSIS

Though the classification recommended by the Tuberculosis Association of India (see appendix) is used in this sanatorium, for the purposes of this inquiry the following classification based on radiological findings was considered more informative and therefore adopted:

Group I.—Exudative or productive lesion (of different stages) without caseation or fibrosis.

Group II.—Mainly a lobar lesion, which is considered to be of an adolescent primary type, clinically running a fulminating course.

Group III.—Mainly a caseous, fibrotic, or mixed lesion—i.e., where irreversible changes have already taken place.

Group IV.—The main lesion is extrapulmonary—e.g., in the gastro-intestinal tract or in the bone—the lung lesion being minimal.

Group V.—The lesion is complicated by pleural effusion.

Group VI.—Miliary tuberculosis. (1) Acute: radiologically there are numerous dots of opacity, of universal distribution in both the lung fields; in a typical case there is miliary disease, the meninges being commonly (2) Chronic: the distribution is universal in both lung being perhaps more marked in the upper zones. The are coarse and less uniform than in acute miliary and generalised miliary disease is uncommon. The may or may not show an old lesion.

RESULTS IN GROUP I

The results obtained in the 27 cases in this group summarised in table I, which shows that the favourable results were obtained in cases either class IIIC, in patients aged 14–25 years, and in more than in men.

The average quantity of streptomycin given cases in class IIIC was 46·1 g. The longest time streptomycin to show favourable results was 48 and the shortest 1 day (3 cases).

Illustrative cases from group I are briefly re below. Every patient within a few days of rec streptomycin showed a well-marked change in becoming optimistic with a sense of well-being. those patients who are shown as having given unfavourable response appreciably improved as re toxæmia, in that their temperature changed from tinuous and remittent to intermittent, with a evening maximum, but they did not maintain improvement. This statement applies to all the group I and therefore is omitted from table I, with mention of concurrent and consequent modes treatment and of common intercurrent diseases such malaria, dysentery, and oral infection.

Illustrative Case-records

Case 1 (IIB).—A woman, aged 20, was admitted on De 1947, with nine months' history of cough, fever, and lo weight. Her temperature was intermittent, with an maximum of 100°F, and her sputum was positive erythrocyte-sedimentation rate (E.S.R.) was 44 mm. in (Westergren). Radiography showed exudative infil in the right mid zone and left hilar region. Treatment artificial pneumothorax (A.P.) and 'Myocrisin' till 1948, produced an unsatisfactory response.

Streptomycin therapy was started on April 29, 1948, continued until 66 g. had been given by July 4, 1948. May 6, 1948, the patient's temperature came down to nor and remained there. On Jan. 31, 1949, she was discha as "disease arrested," with normal temperature, sput negative since July, 1948, E.S.R. 33 mm. in 1 hour, radiolo showing appreciable reduction in both extent and density both lung fields; and having gained 19½ lb. in weight admission. On June 1, 1949, she was well and doing household duties. Period of observation 6 months.

Case 2 (IIB).—A woman, aged 38, was admitted on Nov. 1948, with twelve months' history of cough, fever, and debili and two months' history of pain in the throat and hoarsen

TABLE I—RESULTS OF STREPTOMYCIN THERAPY IN

9, 1948, the evening maximum of the patient's tempera- ell to 99°F, and from July 5, 1948, his temperature ied normal. Radiography on July 9, 1948, showed ion of the focus on the right but increase of effusion ie left oblique fissure; on Sept. 19, 1948, radiography d appreciable resolution of the interlobar effusion. Dec. 2, 1948, the sputum became consistently negative, S.R. fell to 8 mm. in 1 hour, the patient gained 18 lb. ght, and radiography showed evidence of resolution on ft side on Feb. 23, 1949. The patient was discharged b. 23. Period of observation 11 months.

e 16 (group VI(1)).—A man, aged 22, was admitted on , 1949, with fifteen days' history of fever and cough. emperature was 102°F, his sputum negative, and his 50 mm. in 1 hour. The radiological findings were in ig with acute miliary tuberculosis.

ptomycin therapy was started on Jan. 9, and continued 10 g. had been given by Feb. 27, after which the patient ut on myocrisin in addition to sanatorium régime. His rature remained normal from Jan. 25; his sputum ued to be negative, his E.S.R. remained at the same level; graphy showed no change, and he felt well and had $13^{1}/_{2}$ lb. in weight. He is still in the sanatorium. Period servation 9 months.*

se 17 (group VI(2)).—A man, aged 21, was admitted on 26, 1948, with two months' history of fever and produc- cough. His temperature was intermittent, with an ng maximum of 101°F, his sputum was positive, his was 30 mm. in 1 hour, and radiological findings were stent with chronic miliary tuberculosis (autogenous minated type).

eptomycin therapy was started on Sept. 21, 1948, and nued until 42 g. had been given by Jan. 5, 1949. The erature fell and remained normal from Sept. 28, 1948; putum became negative from March 20, 1949; the nt gained 36 lb. in weight; and radiography showed eciable reduction in extent as well as the density of the s in both lungs. The patient is still in the sanatorium, taining his improvement. Period of observation 13 hs.

COMMENT

ryngeal Tuberculosis.—In group I there were 3 cases aryngeal tuberculosis in addition to pulmonary rculosis. One of these, already described (case 2), onded well. The other two (IIIC), with more advanced ionary infection, did not respond so well.

osage.—Double doses of streptomycin were given to tients: 1 received 2 g. to start with, and 3 were given a day to start with, and then doubled to 2 g. because response was not encouraging. Since the increase in ge did not show any benefit it was given up. It is that 1 g. a day is the optimum dose in pulmonary rculosis in an average Indian patient. The average y-weight of the patients was $86^{1}/_{2}$ lb.—the maximum g $138^{1}/_{2}$ lb. and minimum 50 lb. I have already ribed 2 of these 4 cases (nos. 8 and 12).

ases of Special Interest.—Case 10 died of cardiac ire. The patient received 45 g. of streptomycin, left sanatorium with incomplete treatment, and was imitted to die within two hours. In contrast case 2 onded favourably after only 20 g., and that too given rruptedly. In this case the streptomycin was given at the critical stages. As soon as the toxæmia was trolled, the streptomycin was stopped. In this nexion it is of interest to review the other patients received more than twice the average quantity of ptomycin: case 6 (108 g.); case 12 (105 g.); and 14 (106 g.). None of them responded favourably. ne other patients, whose cases are not described ve, were also given doses of streptomycin larger than al. It seems that a limited quantity of streptomycin en in optimum dosage at critical times is more bene- al than is protracted treatment in larger dosage, which may not confer greater benefit. Even those patients who ultimately did not respond favourably showed transient improvement in their general condition. It is our clinical impression that the existence of natural strains of tubercle mycobacteria resistant to streptomycin cannot be ruled out. Indeed, in view of the favourable response obtained with very limited quantities of streptomycin in some cases, it seems probable that the natural susceptibility of different strains of Koch's bacilli to streptomycin varies widely.

Radiology.—Except in acute miliary tuberculosis, an X-ray film of the lung in pulmonary tuberculosis will reveal lesions of different types and of various ages. It is generally possible to spot the older lesions which have been responsible for the more recent spread. It is in these recent ones that early favourable response must be looked for. In the older lesions where fibrosis or caseation has taken place no appreciable response need be expected. Case 12 is an example of this. The usual early evidence of improvement is reduction in the extent of lesions only. Since most of our patients were given myocrisin at some stage, it is considered premature to credit streptomycin wholly and solely for salutary results in the favourable cases. The time-lag between cessation of the treatment and appreciable radiological findings is explained by the fact that necessary tissue changes must occur before they show themselves radiologically. When the pleura are involved, both the absorption of the fluid and/or resolution of pleural thickening are apparent only after months. Case 5 is an example of this. For the purpose of prognosis the type of the lesion, rather than its extent as seen on the film, appears to be more important. The more recent the lesion, the greater the chances of an early favourable response.

CONCLUSIONS

The answers to the queries which our investigation was planned to cover are as follows:

(1) Streptomycin does good in all types of cases in which no irreversible changes have taken place. The best results are to be expected in stages earlier than IIIC. Women seemed to respond better than men, and the age-group of 40 years or more was less favourable.

(2) Our experience is in favour of 1 g. a day in doses of 0·5 g. morning and evening.

(3) There has not been enough time to follow up the cases as laid down by the All India Tuberculosis Association, according to which three years after discharge as "arrested" is the criterion before a patient can be declared cured.

(4) No untoward effects requiring special treatment were noted; a few patients complained of giddiness during the earlier stages of treatment. The only measure adopted to combat it was to suspend the treatment for a while and to renew it later.

(5) Administration of other routine treatments during the course of streptomycin is not contra-indicated but does not seem to confer any additional benefit. *para*-Aminosalicylic acid was tried in one case without advantage.

(6) The adoption of other routine treatments after a course of streptomycin, when the patient has turned the corner from a critical stage, is both necessary and beneficial to maintain results already achieved.

(7) In this series 11 g. of streptomycin was the smallest quantity which gave benefit. It is felt that the best method will be to administer streptomycin during the critical stage and, once the toxæmia has been controlled, to revert to A.P. and other methods of treatment. Therefore the smallest dosage of streptomycin required cannot be rigidly laid down. It differs from patient to patient,

---

nother case of acute miliary tuberculosis, in a boy aged 10 years, admitted on July 25, 1949, and treated with streptomycin for 18 days, resolved completely—as if a mirror had been wiped clear of dust particles. Period of observation 3 months.

debility. She had a remittent temperature, with an evening maximum of 104°F, her sputum was positive, her E.S.R. was 30 mm. in 1 hour, and radiography showed an extensive lesion of lobar distribution in the right upper zone and recent spread to the left upper and both mid zones. She was considered unsuitable for A.P., did not respond to the usual *sanatorium régime, and was therefore put on streptomycin* on May 20, 1948. By July 9, 1948, she had had 45 g. On and after May 27, 1948, her temperature became intermittent, with an evening maximum of 101°F, but her E.S.R. rose to 95 mm., and radiography on June 24, 1948, showed extensive fresh lesions in both fields, with tissue breakdown in the upper zone. She lost $3^1/_2$ lb. in weight and left the hospital on July 9, 1948, only to be readmitted on Aug. 31, 1948, to die within a few hours.

Case 11 (group II).—A girl, aged 19, was admitted on Sept. 8, 1948, with three months' history of cough, fever, and loss of weight. Her temperature was intermittent, with an evening maximum of 102°F, her sputum was positive, her E.S.R. was 102 mm. in 1 hour, and radiography showed an exudative lesion of lobar distribution in the right upper lobe with evidence of tissue breakdown, and on the left a recent spread of tuberculosis in the mid zone. She was unsuitable for A.P., and routine treatment and myocrisin did her no good.

Streptomycin therapy was therefore begun on Sept. 24, 1948, and continued until 15 g. had been given by Oct. 8, 1948. Another short course, of 5 g., was begun on Nov. 19, 1948. The *patient was discharged on April 18, 1949, and her temperature* had been normal and her sputum negative since November, 1948; her E.S.R. was 83 mm. in 1 hour on March 15, and radiography on March 11 gave appreciable evidence of resolution in either mid zone, with crenation at the right apical zone. She gained $21^1/_2$ lb. in weight. Period of observation 7 months.

Case 12 (group III).—A man, aged 51, was admitted on Aug. 17, 1948, with six months' history of fever and cough. His temperature was intermittent, with an evening maximum of 102°F, his E.S.R. was 104 mm. in 1 hour, his sputum was positive, his urine contained 2% sugar, and radiography showed fibrocaseous involvement of whole of the left field and an early exudative focus in the second anterior intercostal space on the right. The glycosuria was controlled without *any effect on the patient's health.*

Streptomycin was given in a double dose to start with, 2 g. a day, from Aug. 17, 1948, and continued until 76 g. had been given by Sept. 22, 1948. This made no difference. Since the patient's liver was slightly enlarged and by previous experience we expected some improvement in his temperature, search was made for *Entamœba histolytica* infection, with success. Treatment for amœbiasis lowered the range of the patient's temperature to a maximum height of 100°F. Streptomycin therapy was again started, 1 g. a day being given from Nov. 3, 1948, and continued until Dec. 1, 1948, by which time 105 g. had been given. The patient's temperature became normal from Nov. 8, 1948, and he went away on Dec. 2, 1948, without waiting to be cured. His temperature had remained normal, his E.S.R. was 102 mm. in 1 hour, his sputum was positive, he had gained $9^1/_2$ lb. in weight, and radiography showed resolution with early calcification in the right field but no appreciable change in the left. The patient is alive and not following a restricted mode of life. Period of observation 14 months.

Case 13 (group IV).—A woman, aged 20, was admitted on May 20, 1948, with six months' history of indigestion and umbilical pain worse after defæcation, the stools being and loose but without blood or mucus. Fifteen days admission she had developed fever, with œdema over dorsum of each foot. Her temperature was remittent, evening maximum of 102°F, her sputum was E.S.R. was 102 mm. in 1 hour, and radiography showed productive lesion in the left subclavicular region. tuberculosis was tentatively diagnosed.

F, female. M, male.

Streptomycin therapy was begun on May 26, 1948. A meal examination was done only on July 8, 1948, because general condition had been low. This confirmed the diagnosis, Sterlin's sign being clearly positive. By July 1948, 66 g. of streptomycin had been given. The temperature gradually came down and remained normal July 17, 1948. *Diarrhœa ceased completely* within a starting treatment. The patient sought discharge on Oct. 1948, when the lung lesion showed appreciable radiography, the E.S.R. had fallen to 9 mm. in 1 hour; had gained 28 lb. in weight, and all other signs and had disappeared. Her present condition is reported to be satisfactory. Period of observation 17 months.

Case 14 (group V).—A man, aged 32, was admitted Jan. 8, 1948, with twelve months' history of fever and cou He had had A.P. elsewhere. His temperature was with an evening maximum of 99°F, his sputum was his E.S.R. was 72 mm. in 1 hour, and radiography hydropneumothorax on the left side, with adhesions at apex, and a spread of tuberculosis to the upper right *There were also enlarged cervical* glands. Sanatorium ré did not benefit the patient, and paracentesis for the effusion produced a sinus.

Streptomycin therapy was started on April 8, 1948, in 10 ml. of distilled water being given *in* the removal of an equal quantity of effusion daily. By Ju 1948, 11·2 g. had been given. On May 27, 1948, the pati temperature became normal, the cervical glands resolved, the sinus cleared, but the sputum remained positive. August the patient's evening temperature rose to 100°F his weight decreased by $6^1/_2$ lb. There was no change in e *the sputum* or the E.S.R. Intramuscular streptomycin now given, up to a total of 30 g. by Sept. *1, 1948.* His perature remained normal from Sept. 8 to Sept. 11, 1948, then rose to 102°F, the sinus reopened, and radiogr showed no improvement. Another course of strepton from Oct. 6, 1948, to Jan. 3, 1949 (106 g.) did not benefit patient, and he went home on Jan. 7 with a pulmonary fis opening into the left pleural cavity (seen after the installat of 'Lipiodol') and recent *involvement* of the right lu Period of observation 12 months.

Case 15 (group V).—A police constable, aged 30, admitted on March *26, 1948*, with five months' history fever, cough, and debility. His temperature was intermitt with an evening maximum of 100·4°F, his sputum was p tive, his E.S.R. was 96 mm. in 1 hour, and radiography sho an effusion *in the left pleural cavity* and into the left obl fissure, and early (Assmann's) focus with *central* cavitat in the 2nd right anterior intercostal space. A.P. given the left side failed; so also did an attempt at left ph evulsion. The pyrexia continued *unabated.*

Streptomycin therapy was started on May 14, 194 continued until 48 g. had been given by July 5, 194 istered. In addition to A.C.T.H., the following unds were tested:

nene-(4)-triol-(17α,20β,21)-one-(3)-diacetate
nane-3,12,20-trione
ethylΔ5-androstendiol-3 (β), 17 (α)
hydroxyprogesterone
hydroxy-11-desoxycorticosterone-21-acetate
xycorticosterone acetate
stanyl acetate.

compounds tested were injected in similar amounts t similar intervals, and since the response, or lack ponse, as the case might be, was parallel in each of hree patients, we shall illustrate by a single case ary.

hite woman, aged 64, was treated in the Nutrition in April, 1949, for nutritive failure (Spies 1947). An ntal finding was a consistently elevated eosinophil-. Careful studies show no evidence of allergies or parasitic tions. Frequent blood determinations during the next nonths showed a total white blood-cell count which l from 6250 to 8142 per c.mm., 32–51% of the cells eosinophils.

en we were ready to initiate the test period, the patient nstructed not to eat after her evening meal and to to the Nutrition Clinic at 7 the following morning. sted from 7 to 8 A.M. and (still under fasting conditions) l white blood-cell count and total eosinophil-count were She was then given 25 mg. of A.C.T.H. intramuscularly. r blood determinations were made at 10 A.M., 12 NOON, P.M. The results are shown in fig. 1. As can be seen, was a definite drop in the eosinophils. By the following ng they had returned to the previous high level. She llowed 72 hours "to rest" and was then given an ion of pregnene-(4)-triol-(17α,20β,21)-one-(3)-diacetate.

owing a 72-hour rest period between injections, this nt received an injection of each of the compounds l above, and in that order. Her eosinophil-count injection of the first three compounds is shown in . and after injection of the remaining four is shown . 2. After all compounds had been tested, she was another injection of A.C.T.H., with the sharp drop e number of circulating eosinophils as shown in .

ter making these tests, it seemed desirable to inister each of the materials to selected patients with acute rheumatoid arthritis. All injections were given intramuscularly and some of them were followed by local irritation, swelling, and pain. These studies, along with others, will be reported subsequently, and it suffices to say now that none of the seven steroids reported here had an ameliorating effect in any way comparable to A.C.T.H., as observed by Hench et al. (1949) and ourselves (Spies and Stone 1949). In only a few instances was there any suggestion of a decrease in the severity of the arthritis, and in these it was not measurable by objective indices such as a return of sedimentation-rates to normal. Hence it will require more time, and more of these materials than we had available, to determine whether they have a slight beneficial effect. In contrast, when the patients were later given A.C.T.H. they began to respond within 24 hours. In each case within 72 hours there was a spectacular decrease in swelling and a great increase in mobility of all the affected joints.

SUMMARY AND CONCLUSIONS

Three persons with chronic eosinophilia of unknown causation were selected for study. Under basal conditions each was injected with purified pituitary adrenocorticotropic hormone (A.C.T.H.), with the result that there was a rapid decrease in the absolute number of circulating eosinophils. Since it is generally thought that the injection of A.C.T.H. results in an increase in cortisone, we injected seven chemical substances somewhat related in structure to cortisone. None of these compounds caused a decrease in the number of circulating eosinophils, which shows that this test has some specificity. We have tested these sterols on persons with rheumatoid arthritis and have not observed improvement which is at all comparable to that following the injection of A.C.T.H.

depending on various factors, such as age, sex, stage, class, and group of case. *Haphazard administration of streptomycin in private practice, unless backed by institutional or expert advice, should be forbidden in India.* Apart from the fact that streptomycin-resistant strains exist in nature, there is the danger of dollar drain which India cannot afford unless well fortified by successful results. Last year £3,000,000 was spent in India on streptomycin.

SUMMARY

47 cases of tuberculosis treated with streptomycin are analysed. These cases were separated into six groups: group I exudative, group II pneumonic, group III fibrocaseous, group IV intestinal, group V pleural in addition to pulmonary, and group VI miliary—(1) acute, and (2) chronic.

Of 27 cases in group I, 11 gave a favourable response; of 4 in group II, 2; of 3 in group III, none; of 5 in group IV, 5; of 4 in group V, 3; of 1 in group VI(1), 1; and of 3 in group VI(2), 2.

The shortest period of observation was 6 months and the longest 17 months.

Cases less advanced than IIIC responded most favourably, women better than men, and the age-group 14–25 came out best.

Case-records of illustrative cases are given, and a questionary set before the investigation is answered.

Administration of streptomycin other than institutional, or other than by experts, is deprecated.

We thank Colonel S. L. Bhatia, F.R.C.P., Surgeon-General with the Government of Madras, for permission to publish this paper, and the matron, sisters and nurses for their always willing coöperation.

Appendix

The classification of cases of pulmonary tuberculosis as recommended by the All India Tuberculosis Association is as follows:

Stage I.—*A lesion affecting not more than one zone or, if there is a lesion overlapping two zones, the extent of the total lesion should not cover more than one zone.* If there is *bilateral affection, it should be grouped in this stage only if the lesion is not below the clavicle on one of the sides and the total extent of the lesions is less than one zone.* No case with cavities should be grouped in this stage. If there is complete pneumonic consolidation of one zone, even if it is confined to one zone only, it should be grouped in stage II.

Stage II.—*In unilateral disease, the lesion should not extend* to more than two zones. In bilateral disease the lesions should *not extend to more than one zone on each side*, and the total extent should not be more than the equivalent of two zones. If there is cavitation, it must be limited to a single cavity the diameter of which is not more than 2 cm. If there is no X ray all cases with cavitation should be placed in stage III. If two zones are completely consolidated, even without cavitation, the lesion should be grouped in stage III.

Stage III.—All lesions more advanced than those grouped in stage II, and all with *a cavity larger than 2 cm. in diameter*, or with multiple cavities; and all cases with spontaneous pneumothorax associated with an active tuberculous lesion in the lung.

In addition to the above, primary considerations according to the lung lesion, complications both tuberculous and non-tuberculous have to be taken into account.

Such tuberculous complications as laryngeal tuberculosis, tuberculous enteritis, extensive tuberculosis, *osteo-articular* tuberculosis, renal tuberculosis, pleurisy with effusion, polyserositis, and meningeal tuberculosis, *and* such non-tuberculous complications as diabetes, kala-azar, and pregnancy must be taken *into consideration* in classification. Patients with these complications are generally put one stage down—e.g., a patient classified in stage I according to the anatomical extent of the lung disease would be classified in stage II if he has also laryngeal tuberculosis. If the complication is very severe, or if there is more than one complication, the patient is classified in stage III.

The degree of systemic effect should be noted end of a week's observation, after which the stages be subdivided into A, B, and C, as follows:

A.—Constitutional disturbances, absent or slight, judged *mainly* by *temperature*, pulse-rate, influence nutrition and strength, wasting, E.S.R., and blood As regards temperature, the average maximum in the over a week after half an hour's rest in bed should not 99°F oral or 99·8°F rectal; the average pulse-rate week should not ordinarily exceed 90 per min.; the and blood picture should not vary much from the

B.—Constitutional disturbance moderate—i.e., *between A and C. No serious complications affecting* organ or tissue seriously impairing function, local or *tutional.*

C.—Severe constitutional disturbance. The average of maximal temperature over a week with the patient at exceeds 100·4°F oral, 101°F rectal; the average over a week exceeds 96 per min.; the E.S.R. is high and blood picture considerably deviated from normal.

A SCREENING TEST OF CHEMICAL COMPOUNDS FOR PITUITARY ADRENOCORTICOTROPIC HORMONE ACTIVITY *

From the Department of Nutrition and Metabolism, No western University, and the Nutrition Clinic, Hillman Hosp Birmingham, Alabama

Thorn, Forsham, Prunty, and Hills (1948) showed in normal subjects the circulating eosinophils consistently after the injection of purified pitui adrenocorticotropic hormone (A.C.T.H.), and demonstrat the usefulness of this test in diagnosing adre *insufficiency.* Since the A.C.T.H. stimulated the adre cortex and resulted in the increased production of adrenal sterol 'Cortisone' (17-hydroxy-11-dehydr corticosterone) in the normal person but not in the per with adrenal insufficiency, it seemed worth determin the effect on the circulating eosinophils of selected ster injected under the same conditions as A.C.T.H. For study we selected three patients with eosinophilia.

These three patients had all been studied *for at* le six months. During this time the eosinophil-count each case had never been less than 2000 per cubic metre by absolute count or less than 20% of the white blood-cells by differential count using Wrig stain. *The patients ate no food* during the hours preceding the injection. At 8 A.M., under *conditions*, white *blood*-cell counts, differential and absolute eosinophil-counts by the method of Thor *et al. (1948)* were *done.* Immediately after the 8 A count the A.C.T.H. or the test compound (suspende *in saline or in benzyl alcohol)* was injected intra muscularly into the buttocks. The blood-counts wer done again *at* 10 A.M., 12 NOON, *and* 2 P.M. After the injection of A.C.T.H., three days were allowed *to* elap and the test substances were *given* three days apar After all the test substances had been administered, thre days were allowed *to* elapse *and* A.C.T.H. was aga

(a)—Loss of thermoregulatory sweating in patient after thoraco-bar sympathectomy (left, T.10-L.3; right, T.4-L.2), 12 weeks r operation on left side and 3 weeks following that on the right.

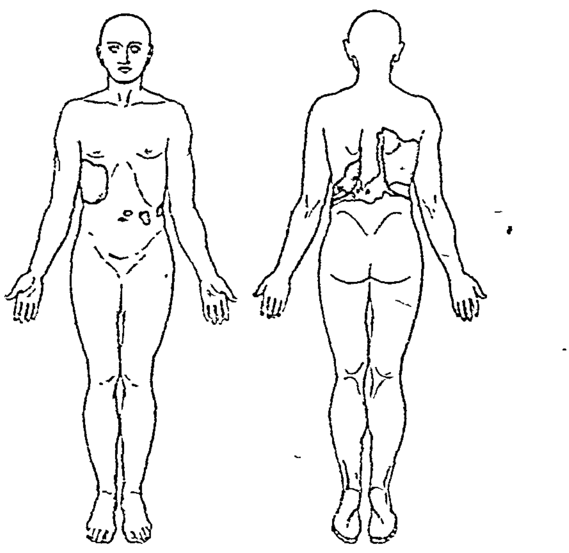

Fig. 2(b)—Absence of sweating in the patient figured in 2(a) following injection of carbachol.

tomy ultimately decreases so that from 2 weeks to nths postoperatively it ceases to occur." This test been applied in one of our cases.

g. 2(a) shows the thermoregulatory sweat pattern patient who had paravertebral sympathectomy L.2 performed on the right side and T.10–L.3 -L.3) on the left. Six days after this test, instead at being applied, this patient was given an injection cholinergic drug (carbachol 0·5 mg. intramuscularly). his occasion—fig. 2(b)—the whole of the lower lumbar sacral regions showed sweating activity but the sweating area on the thorax persisted though it was extensive than in the first test and consisted only chain of islands on the left side. In both these on this patient the observations with the skin-tance meter were confirmed by the quinizarin sweat (Guttman 1947) and have been photographed. As use sweating was not induced, deeply stained patches not produced everywhere, but the pore of each vidual active gland was stained blue. The patterns weating in each instance were similar but that of skin-resistance method showed the presence of slight ating one to two centimetres beyond the margin of quinizarin reacting areas.

AN ALTERNATIVE AUTONOMIC PATH ?

he existence of a sudomotor "escape" area in the 2, and 3 dermatomes after thoracolumbar sympa-ctomy, as described above, has already been recorded chter and Woodruff 1945, Ray and Console 1948, rd 1948). It suggests to us that an alternative omotor pathway persists intact after the operation. y and Console, indeed, have already indicated a ief in the existence of such an alternative pathway. ey did not, however, track it down further than to ite that

> "the residual pathways to the T.12–L.3 area arise from the corresponding anterior spinal roots. The first lumbar roots seem to play the predominant rôle, but as the pathways can be blocked by tetraethylammonium chloride the usual preganglionic and postganglionic fibres must be present. The position of the ganglion cells is uncertain, but may be in the plexus about the aorta, behind the psoas muscle, or in the lumbar nerves themselves. The fibres are not distributed to the T.12–L.3 dermatomes via the periarterial sympathetics, but enter the nerves of the lumbar plexus close to their points of origin and reach their final distribution via these nerves."

Hyndman et al. (1948) subsequently criticised Ray and Console for postulating a system of fibres hitherto unrecognised in the literature. Figs. 2(a) and (b) indicate to us that in this patient there was postganglionic (and preganglionic) denervation of the sweat-glands in the lower thoracic dermatomes but retention of postganglionic function in the lower lumbar and sacral regions. As, however, T.12–L.3 dermatomes showed continued thermoregulatory sweating, these segments must have retained the normal, or at least part of the normal, preganglionic and postganglionic innervation of the sweat-glands.

OBSERVATIONS ON THE FŒTUS

Our clinical observations, and Ray and Console's results, led us to examine a large number of human embryos and fœtuses in an attempt to locate the autonomic cells of the residual pathway. Much of this material is stained with silver impregnation methods in which the sympathetic nervous system is often demonstrated with diagrammatic clearness. Examination of this

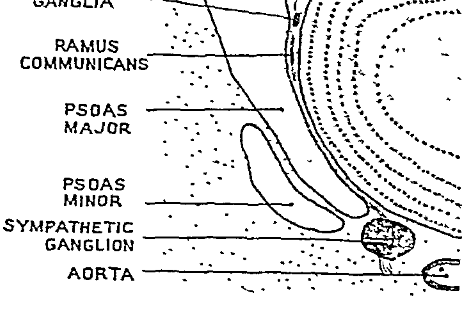

Fig. 3—Camera-lucida drawing of section through the level of the right 2nd lumbar sympathetic ganglion in a 100 mm. C.R. length human fœtus: the section shows five intermediate ganglia in relation to the anterior primary division and a ramus communicans.

PARTIAL RETENTION OF AUTONOMIC FUNCTION AFTER PARAVERTEBRAL SYMPATHECTOMY

(INTERMEDIATE LUMBAR SYMPATHETIC GANGLIA AS THE PROBABLE EXPLANATION)

J. D. Boyd
M.A. Camb., M.D., M.Sc. Belf.
PROFESSOR OF ANATOMY IN THE UNIVERSITY OF LONDON

P. A. G. Monro
B.A., M.B. Camb.
DEMONSTRATOR OF ANATOMY

From the Department of Anatomy, London Hospital Medical College

During an investigation of the effect of thoracolumbar sympathectomy on autonomic function we have observed that an "escape" area of sweating constantly persists in the lower abdomen and front of the thighs, corresponding to the 1st and 2nd lumbar segmental dermatomes and possibly including the 12th thoracic and the 3rd lumbar. The operations were performed in two stages, in the neurosurgical unit of the London Hospital, on patients with severe benign and malignant hypertension. Usually the 8th thoracic to the 3rd lumbar sympathetic ganglia inclusive, together with the splanchnic nerves, were removed by an extrapleural approach, and more recently the resection has extended from the 4th thoracic to the 3rd lumbar ganglia. Clips were placed on the upper and lower ends of the remaining paravertebral chain and the levels checked by radiography. Therefore, according to current opinion, if the lower limit of the thoracolumbar outflow of the sympathetic is taken as the 2nd lumbar nerve (or rarely the 3rd), as confirmed in man by Sheehan (1941) and Pick and Sheehan (1946), such an operation should achieve a complete section of postganglionic fibres (and, indeed, preganglionic fibres) between the levels of T.8 (or T.4) and L.3 inclusive, and section of preganglionic fibres only for L.4 and lower segments.

CLINICAL OBSERVATIONS

Patients were examined, after inducing gentle sweating in a heating cabinet, by the electrical skin-resistance method using a microammeter and 9–18 volts D.C. (Accurate and precise observations will not be obtained unless the patient is sufficiently heated to induce sweating and unless these higher voltages are employed.)

Typical patterns in two patients are shown in figs. 1 and (*b*). They agree fairly closely with the illustrations lished in a well-reasoned paper by Ray and Console (1 though in our cases the borders of the "escape are more variable and asymmetrical, frequently "islands and peninsulas." These patients were examined after each operation but were seldom enough before the twelfth day. A dye sweat test usually performed, for this requires longer heating, is not well tolerated by these patients. Sweat after the first and second operations and at later up to nine months show fairly close agreement variations as occur are probably best explained re-innervation from neighbouring sweating areas, or *later fibrosis at the site of ganglionectomy,* extension of a non-sweating area.

In general we have found that after tho sympathectomy, thermoregulatory sweating is a belt around the lower thorax and upper though occasionally it may persist over the spine is fairly profuse over the lower abdomen, groin, perineum, and upper buttock (lumbar dermatomes) on the front of the thigh and inner side of the calf, it is absent on the leg below this level and on the dermatomes except around the perineum. That is, is segmental autonomic denervation from T.8 (or T caudally but sparing of segments T.12–L.3. These terns show the anatomical limits of sweating; the of sweating on the front of the thigh is less than before operation. This suggests to us probably there is *only* partial denervation of the glands in this area. But it is also possible that are in part supplied by overlap from the seg above.

A pharmacological test was originally suggested *List and Peet (1938)* as a method for disting between preganglionic and postganglionic denervatio sweat-glands. Further studies have been made Hyndman and Wolkin (*1941*) and by these investiga with van Allen (1948) who used pilocarpine and mech on *cases of cervicothoracic sympathectomy.* observed that if the ganglion cells and postgangli fibres are intact (i.e., following preganglionic section o these drugs in small dosage will *continue* to c sweating in areas which no longer show thermoregula sweating and in their opinion, this is due to action the neuroglandular junction (end plate). They state that "drug sweating *after* postganglionic sym

allergists and septic-focus finders, and is outspoken
ɜnever he feels so inclined.

e Vitamins in Medical Practice

J. SHAFAR, M.D., M.R.C.P., D.P.H. London: Staples Press. 1949. Pp. 383. 25*s*.

ANY book with 1684 references in it must command
pect, and Dr. Shafar wins our admiration for his skill
making so good a story out of them. His first hundred
ges or so contain accounts of the various accessory
ɔd factors identified within the last thirty years:
are there, from the veterans like A and D to the
est recruits to the B complex. The rest of the book
res us the picture the other way round, so to speak.
rst the specific diseases known to be due to vitamin
ficiencies are presented, and secondly the various
partments of medicine are taken as the centre of interest
ıd the importance of vitamins to them is discussed.
hus we have sections on the vitamins in pregnancy,
hepatic physiology and pathology, in hæmatology,
ıd in relation to disorders of the skin and hair; there
e even sections on the vitamins in surgery, in aural
ısorders, and in allergic conditions. The book, there-
ɔre, sets out to be both a treatise on the vitamins and a
ork of reference for surgeons, dermatologists, urologists,
ardiologists, and all the other specialists who want
o know what the latest discovery in the world of vitamins
has to do with them. It is well written, the index is good, and it is likely to have a wide appeal.

It may seem ungrateful to ask the author for still more, but some historical information would have added both interest and balance, and there are curious little omissions here and there, even about *le dernier cri*. There is nothing, for instance, about the toxicity of polar-bear liver in the section on vitamin-A overdosage, and there is no reference to phytic acid and little to any of the antivitamins. Also there are some mistakes in the references. No man can be a master of all the subjects covered by such a work, and the text is essentially a compendium of knowledge rather than a critical review; but it is a useful compendium, and many will have occasion to thank the author for his industry.

Contribución del Coeficiente Citológico a la Fisiología y Patología de la Correlación Hipofisotiroidea

ESTANISLAO DEL CONTE, M.D., institute of general anatomy and embryology, Faculty of Medical Sciences of Buenos Aires. Buenos Aires: El Ateneo. 1949. Pp. 87.

THIS monograph describes a method of evaluating thyroid function by counting intracellular droplets in sections prepared by the freeze-drying technique. The guineapig's thyroid, treated in this way, has proved to be a delicate index of thyrotropic activity, and can be used to assay normal and pathological human serum. The author's results indicate that the concentration of thyrotropic hormone is low in patients with thyrotoxicosis but rises to normal after treatment. The behaviour of intracellular droplets in the thyroids of other species is also described and illustrated. and the relevant literature is reviewed. Anyone working in this specialised field will find much to interest him.

Society and its Criminals

PAUL REIWALD, doctor of jurisprudence; reader i
criminology, University of Geneva. London: Heineman
Medical Books. 1949. Pp. 315. 21*s*.

Sir Norwood East's *Society and the Criminal*[1] mig
perhaps be regarded as the epitome. if not the manifes
of conservative English penal psychiatry. Dr. Reiwa
book, though it is in no sense a specific reply to
work of the conservative-progressive school, pres
the grounds on which such a reply might be b
and presents them in a form which must com
attention. It contains no new material—the a r
superscribes it with the words of Goethe's Mephisto :
"You must say it thrice"—but it marshals its c ne
of non-analytic and administrative penal psycho in
a highly compact and compelling form.

The fundamental weakness of conservative p gy
is, for Dr. Reiwald, its failure to criticise th ace
of the attitudes which society, the State, and t blic
present to crime. The criminal, his activities his
punishment are the focus of emotional forces in blic
and the judge, which Dr. Reiwald trace ugh
comparative anthropology and the peculia of
crime in contemporary fiction. These emoti rces.
for which institutional law and its social a are
a mask. are too well established, both by t dian
approach which Dr. Reiwald adopts, and amon
observation, to be ignored. To the m ptical
penologists who *still* regard analytical s *to*
dispose of healthy wickedness as speculat s able
to point out that methods of treatment ng *no*
element of concealed aggression are. o sis of
growing experimental evidence, the sole ans *of*
re-creating the social sense of delinque *effect*
there is today an unequivocal answer estion,
what can be substituted for aggression l law ?
—non-violence and self-government ans of
education." The only serious weak he case
which he presents lies, perhaps, in his come to
terms with the problem of political a mani-
festation of aggressive behaviour, by e frame-
work of institutional punishment is He con-
siders, for example. that judicial might be
retained in future criminal codes. ement of
retribution and aggression had bee l from it.
It is interesting that the gap be Reiwald's

INTERMEDIATE SYMPATHETIC GANGLION

Fig. 4—Diagram to show effect of thoracolumbar sympathectomy on connexions of intermediate ganglia. Preganglionic fibres indicated as continuous lines; postganglionic fibres as interrupted lines. The rectangle indicates the tissue removed in the sympathectomies. Preganglionic fibres in this instance are shown in the 3rd lumbar root.

material revealed the presence of numerous "intermediate" sympathetic ganglia, of varying size and distribution, in the course of the rami communicantes passing between the lumbar sympathetic ganglia and the corresponding anterior primary rami of the lumbar nerves.

These intermediate ganglia are situated for the most part dorsal to the psoas muscle or between its posterior fibres of origin (fig. 3). They are on the course of the more dorsal of the rami communicantes of L.1, 2, and 3—i.e., the rami considered to be of the grey variety. The ganglia may be at any point along the rami, either near the sympathetic chain, in an intermediate position, or close to the lumbar nerves; indeed, some of them are on the surface of, or embedded in, the anterior primary rami. Such ganglia can also be found on the rami communicantes of L.4 and 5. The position of many of these intermediate ganglia is such that they would necessarily escape removal in the usual operation of thoracolumbar sympathectomy. It is clear (see fig. 4) that removal of the sympathetic chain isolates the intermediate ganglia associated with L.4 and 5 from preganglionic impulses unless there happen to be connexions outside the sympathetic chain. The intermediate ganglia associated with L.1, 2, and possibly 3 (and equivalent ones on T.12) may, however, be unaffected by such operations if, as we believe, their preganglionic fibres pass to them directly from the corresponding lumbar nerves without first passing in the white rami to the sympathetic chain. It is, of course, these very segments that show the retention of sudomotor activity. On studying the relevant literature we have found that Wrete in several contributions (1935, 1941, 1943a and b), has given a full description of these intermediate ganglia. We have followed him in using the term "intermediate" for them. These ganglia have also been described by Pick and Sheehan (1946), who use the adjective "intermediary" for them. In our opinion the discrepancies in loss of sudomotor activity after sympathectomies of the type described here are completely explained by the arrangement distribution of these intermediate ganglia of Wrete

COMMENT

Our findings agree with Wrete's report that intermediate ganglia are extremely variable and metrical. This variability will readily account for irregular patterns in our observations, and for "islands" and "peninsulas" of sweating or non-sweat As far as we have yet been able to determine from embryological material it does not appear that ganglia have any visceral connexions. We can offer evidence that they are concerned in the nerve-supply the kidney or the splanchnic bed.

We have also verified on our fœtal material anatomical findings of Skoog (1947) on similar in mediate ganglia in the cervical region. Indeed, in opinion, the presence of such cervical interme ganglia is a better explanation of the atypical sudom responses following sympathectomies in the region than that advanced by Hyndman et (1948).

As the intermediate sympathetic ganglia here are relatively inaccessible to the surgeon, and th precise location is uncertain, it seems likely that thoracolumbar or lumbar sympathetic denervation only be obtained by anterior rhizotomy. Further may show that such a drastic procedure is only nec in particular regions, and on a limited scale, in asso with orthodox sympathectomy. Such combined o tions have already been performed by Ray and Co They state that section of the anterior roots of T L.1, and 2 "does not result in any recognisable defects in the lower extremities." An alternative to radical procedures might be the paravertebral in of phenol at the levels of L.2 and 3 which we observed to produce loss of sweating in at least part "escape" area.

A more detailed and further study of these and autonomic investigations on these patients, and of intermediate ganglia, will be published in due course.

SUMMARY

1. The existence of a sudomotor "escape" belt paravertebral thoracolumbar sympathectomy has verified in the dermatome segments of T.12–L.3.

2. Attention is drawn to the presence of intermedia sympathetic ganglia at these segmental levels.

3. It is suggested that these intermediate gan together with their associated preganglionic connection and postganglionic fibres afford the anatomical explanation for the retention of sweating in the "escape" belt

4. Intermediate ganglia are also found in the cervical and in the lower lumbar regions. In the neck they may be the explanation of atypical loss of autonomic function after cervicothoracic sympathectomy. Thoracolumb sympathectomy (T.4–L.3) will deprive the intermedia ganglia of the 4th and 5th lumbar segments of the preganglionic connections.

ADDENDUM

Since this paper was written we have had the opportunity of examining post-mortem material from one patient in our series who showed a similar sudomotor escape pattern. The lower level of resection of the paravertebral sympathetic chains included each third lumbar ganglion. Microscopic examination of this material has confirmed the presence of many intermedia ganglia in the rami communicantes and primary divisions of the first and second lumbar nerves. Most of the cells of these ganglia appear normal but some show changes suggestive of degeneration. This degeneration may be grade, due to section of the corresponding post- ionic fibres.

are especially grateful to Mr. D. W. C. Northfield. on in charge of the neurosurgical unit at the London tal, for permission to examine patients under his care or much advice and encouragement.

No man can be a master of all the subjects covered by such a work, and the text is essentially a compendium of knowledge rather than a critical review; but it is a useful compendium, and many will have occasion to thank the author for his industry.

Contribución del Coeficiente Citológico a la Fisiología y Patología de la Correlación Hipofisotiroidea

ESTANISLAO DEL CONTE, M.D., institute of general anatomy and embryology, Faculty of Medical Sciences of Buenos Aires. Buenos Aires: El Ateneo. 1949. Pp. 87.

THIS monograph describes a method of evaluating thyroid function by counting intracellular droplets in sections prepared by the freeze-drying technique. The guineapig's thyroid, treated in this way, has proved to be a delicate index of thyrotropic activity, and can be used to assay normal and pathological human serum. The author's results indicate that the concentration of thyrotropic hormone is low in patients with thyrotoxicosis but rises to normal after treatment. The behaviour of intracellular droplets in the thyroids of other species is also described and illustrated, and the relevant literature is reviewed. Anyone working in this specialised field will find much to interest him.

Society and its Criminals

PAUL REIWALD, doctor of jurisprudence; reader i criminology, University of Geneva. London: Heineman Medical Books. 1949. Pp. 315. 21*s*.

Sir Norwood East's *Society and the Criminal* [1] mig perhaps be regarded as the epitome, if not the manifes of conservative English penal psychiatry. Dr. Reiwa book, though it is in no sense a specific reply to work of the conservative-progressive school, pre the grounds on which such a reply might be b and presents them in a form which must com attention. It contains no new material—the a r superscribes it with the words of Goethe's Mephisto : "You must say it thrice"—but it marshals its ne of non-analytic and administrative penal psycho in a highly compact and compelling form.

The fundamental weakness of conservative gy is, for Dr. Reiwald, its failure to criticise th ce of the attitudes which society, the State, and t lic present to crime. The criminal, his activities his punishment are the focus of emotional forces in lic and the judge, which Dr. Reiwald trace ugh comparative anthropology and the peculia of crime in contemporary fiction. These emoti ces. for which institutional law and its social a are a mask, are too well established, both by t dian approach which Dr. Reiwald adopts, and mon observation, to be ignored. To the m tical penologists who still regard analytical s to dispose of healthy wickedness as speculat s able to point out that methods of treatment ng no element of concealed aggression are, is of ans of growing experimental evidence, the sol effect re-creating the social sense of delinq stion, there is today an unequivocal answ l law ? ans of what can be substituted for aggres e case ome to —non-violence and self-governm mani- education." The only serious w frame- which he presents lies, perhaps, i con- terms with the problem of p nt be festation of aggres beha rom of work of institutional puni it. iwald's siders, for example, th 1053. retained in future crir retribution and aggre It is interesting th

INTERMEDIATE SYMPATHETIC GANGLION

Fig. 4—Diagram to show effect of thoracolumbar sympathectomy on connexions of intermediate ganglia. Preganglionic fibres indicated as continuous lines; postganglionic fibres as interrupted lines. The rectangle indicates the tissue removed in the sympathectomies. Preganglionic fibres in this instance are shown in the 3rd lumbar root.

material revealed the presence of numerous "intermediate" sympathetic ganglia, of varying size and distribution, in the course of the rami communicantes passing between the lumbar sympathetic ganglia and the corresponding anterior primary rami of the lumbar nerves.

These intermediate ganglia are situated for the most part dorsal to the psoas muscle or between its posterior fibres of origin (fig. 3). They are on the course of the more dorsal of the rami communicantes of L.1, 2, and 3—i.e., the rami considered to be of the grey variety. The ganglia may be at any point along the rami, either near the sympathetic chain, in an intermediate position, or close to the lumbar nerves; indeed, some of them are on the surface of, or embedded in, the anterior primary rami. Such ganglia can also be found on the rami communicantes of L.4 and 5. The position of many of these intermediate ganglia is such that they would necessarily escape removal in the usual operation of thoracolumbar sympathectomy. It is clear (see fig. 4) that removal of the sympathetic chain isolates the intermediate ganglia associated with L.4 and 5 from preganglionic impulses unless there happen to be connexions outside the sympathetic chain The intermediate ganglia associated with L.1, 2, and possibly 3 (and equivalent ones on T.12) may, however, be unaffected by such operations if, as we believe, their preganglionic fibres pass to them directly from the corresponding lumbar nerves without first passing in the white rami to the sympathetic chain. It is, of course, these very segments that show the retention of sudomotor activity. On studying the relevant literature we have found that Wrete in several contributions (1935, 1941, 1943a and b), has given a full description of these intermediate ganglia. We have followed him in using the term "intermediate" for them. These ganglia have also been described by Pick and Sheehan (1946), who use the adjective "intermediary" for them. In our opinion the discrepancies in loss of sudomotor activity after sympathectomies of the type described here are completely explained by the arrangement distribution of these intermediate ganglia of Wrete

COMMENT

Our findings agree with Wrete's report that intermediate ganglia are extremely variable and metrical. This variability will readily account for irregular patterns in our observations, and for "islands" and "peninsulas" of sweating or non As far as we have yet been able to determine from embryological material it does not appear that ganglia have any visceral connexions. We can evidence that they are concerned in the nerve-supply the kidney or the splanchnic bed.

We have also verified on our fœtal material anatomical findings of Skoog (1947) on similar mediate ganglia in the cervical region. Indeed, in opinion, the presence of such cervical ganglia is a better explanation of the atypical responses following sympathectomies in the region than that advanced by Hyndman et (1948).

As the intermediate sympathetic ganglia here are relatively inaccessible to the surgeon, and precise location is uncertain, it seems likely that compl thoracolumbar or lumbar sympathetic denervation only be obtained by anterior rhizotomy. Further may show that such a drastic procedure is only nec in particular regions, and on a limited scale, in asso with orthodox sympathectomy. Such combined tions have already been performed by Ray and C They state that section of the anterior roots of T L.1, and 2 "does not result in any recognisable defects in the lower extremities." An alternative to radical procedures might be the paravertebral in of phenol at the levels of L.2 and 3 which we observed to produce loss of sweating in at least part of "*escape*" area.

A more detailed and further study of these and oth autonomic investigations on these patients, and of intermediate ganglia, will be published in due course.

SUMMARY

1. The existence of a sudomotor "escape" belt paravertebral thoracolumbar sympathectomy has verified in the dermatome segments of T.12–L.3.

2. Attention is drawn to the presence of intermedi sympathetic ganglia at these segmental levels.

3. *It is suggested that these intermediate gang* together with their associated preganglionic connectio and postganglionic fibres afford *the anatomical explan* tion for the retention of sweating in the "escape" be

4. Intermediate ganglia are also found in the cervic and in the lower lumbar regions. In the neck they ma be the explanation of atypical loss of autonomic functio after cervicothoracic sympathectomy. *Thoracolumb* sympathectomy (T.4–L.3) will deprive *the intermedia* ganglia of the 4th and 5th lumbar segments of the preganglionic connections.

ADDENDUM

Since this paper was written we have had the opportunity of examining post-mortem material from one patient in our series who showed a similar *sudomotor* escape pattern. The lower level of resection of the paravertebral sympathetic chains included *each* third lumbar ganglion. Microscopic examination of this material has confirmed the presence of many intermediate ganglia in the rami communicantes and primary division of the first and second lumbar nerves. Most of the cell of these ganglia appear normal but some show change suggestive of degeneration. This degeneration may be

Now from 1 injection of PROLOPEN

...high initial penicillin blood level

...prolonged penicillin activity

Newest addition to the new range of Glaxo penicillin preparations, PROLOPEN is a suspension of crystalline sodium penicillin G and procaine penicillin G in arachis oil with aluminium stearate. A 1 cc. injection of Prolopen provides both an early, powerful penicillin action, rising to a peak level of 1.0 to 2.0 units per cc., and a *sustained* effect lasting 24 hours or more.

This combined action of Prolopen is particularly valuable when treating conditions in which more resistant organisms are implicated (staphylococci, for instance) — organisms which cannot always be adequately countered by an oily injection of procaine penicillin alone.

GLAXO

Available in 10 cc. vials **PROLOPEN**

GLAXO PENICILLIN PRICES REDUCED as from Monday, October 3.

ANDROGENS

in Gynaecology

The rationale for the use of androgens in the female is based on their ability to produce a reflex pituitary inhibition. Androgens may therefore be substituted in certain conditions where œstrogens are contra-indicated or have been tried and found ineffective. The clinical application of androgens in the female includes hypermenorrhœa, whether functional or of menopausal origin, mastodynia, pre-menstrual tension, dysmenorrhœa, frigidity and more recently, the treatment of advanced carcinoma of the breast.

The British Schering range of androgenic preparations includes:

'TESTOVIRON' for parenteral administration; it is an oily solution of testosterone propionate.

'ORAVIRON' for oral and sublingual therapy, which in adequate dosage reproduces all the known effects of parenterally administered androgen.

'TESTOVIRON' Ointment is available for topical application when a local effect only is required.

criminal and social psychiatry is precisely that which some modern educationists in this country, especially Herbert Read, have been trying to bridge by means of a sociological anarchism.

This book, which will undoubtedly provoke detailed criticism and study, is particularly interesting to English penologists for its contrast with the more conservative viewpoint, for its interpretation of the recent debates upon the abolition of the death penalty, and for the sharpness with which it reveals the impact of penal psychiatry on political thought. In coming to recognise that the criminal subserves an essential function in the mental dynamics of modern society, we come to accept a revolution which extends far outside the walls of the prison.

English Social Services

Methods and Growth. EMMELINE W. COHEN. London: Allen & Unwin. 1949. Pp. 158. 8*s.* 6*d.*

THIS is a rather fluffy little book, written by American ladies for American ladies. Miss Cohen and her friends, having read portions of English social history during the 19th century, have tried to present them as a scientific account of the evolution of our modern social provision for children and the poor in this country. They tell some moving stories of the sad conditions which prevailed 100 years ago among neglected, handicapped, and slum children, and they describe some of the pioneer movements of voluntary social service. But the book peters out when it comes to present-day schemes, Acts of Parliament, and statutory services that really matter. It touches on the old poor-law system, but does nothing to explain the evolution of that system, thanks to the work of the Webbs, Beveridge, and others, into our modern specialised social services. Even before July 5, 1948, this book would have had no right to its over-grand title.

Der Arzt der Persönlichkeit

Dr. Med. ERNST SPEER, Dozent für Psychiatrie und Neurologie, Lindau, Bodensee. Stuttgart: Thieme. 1949. Pp. 285. D.M. 26.

THIS book with the rather pompous title "Physician Personality" proves to be a readable and lucid position of the methods and tasks of medical psycho- erapy written for the student of psychiatry. The hor thinks the time of rivalry among schools in this d is over, and eclecticism the rule for the modern chotherapist. He has to choose from all available hods the one most suited to the individual patient. d's and Jung's teaching are presented with equal ence, Adler with much criticism; but such methods he therapeutic interview, suggestion, hypnosis, ation techniques, and painting and drawing, with indications and limitations, are fully discussed. has his own method of "contact psychology" for atment of neurotic sex inhibitions. His weakness somewhat vague and diffuse psychopathology ed by Kretschmer and Jung, but also by French try of the last century. Severe neuroses not to psychotherapy indicate "degeneration" and cept is also applied to schizophrenia. One may this as a relic of the Nazi attitude (of which is conspicuously free in all other respects) the psychiatric patient.

A l Survey of the British Pharmacopœia, 1948

n: Pharmaceutical Press. 1949. Pp. 79. 5*s.* 6*d.*

su a series of authoritative monographs on an interest to the student of modern pharmacy trermaceutical chemist. It is significant of the puelopments in this composite science that the sle t and the biochemist may dip into this of ne and find in it an interesting presentation nevects of the pharmaceutical chemistry of cistpreparations. The senior hospital pharma- parciate the practical value of the section on witections and tablets; and the book is not and t even for the entomologist. A thoughtful consive essay on the new pharmacopœia is Brit Dr. C. H. Hampshire, secretary of the copœia Commission.

Understand Your Diabetes (London: Oxford Press. 1949. Pp. 146. 7*s.* 6*d.*) and **A Handbook Diabetes Mellitus and its Modern Treatment** (4th Calcutta: Dhur & Sons. 1949. Pp. 227. Rs. 10/8). specialists are always producing small books for their leagues or patients, and here are two more. From John W. Caldwell gives us the first—a very adequate book, telling what diabetes is, and giving advice on insulin, and so on. Dr. J. P. Bose, of Calcutta, in the edition of a much more comprehensive book, writes for Indian doctors. Unfortunately the doses of insulin given are not discussed, and this whole subject is dismissed in half a page. The food tables, however, the analyses of Indian foods as well as English, are larly interesting. Unfortunately they are arranged in old-fashioned way, giving food values in terms of per oz. which makes their practical use a burden: e.g., beaten rice (chira) = 22·1 g. carbohydrate, 1·9 g. 0·4 g. fat.

Transactions of the Ophthalmological Society of United Kingdom (vol. 67. London: J. & A. 1948. Pp. 530. 40*s.*).—This volume for the year 1947 been delayed owing to difficulties in printing. It the papers read at the annual congress of the society those of the Oxford Ophthalmological Congress, the N England Ophthalmological Society, and the Midland, and Irish Ophthalmological Societies. The papers cover a wide field and there is much useful information contracted sockets, rhinology in relation to or corneal bloodstaining, and experimental tumours of the The outstanding contribution, however, is that on the mental transplantation of eyes. Dr. L. S. Stone, professor anatomy at Yale University, discussed this work in his memorial lecture. For the past twenty years he has engaged on these researches, and he was able to report and show films of, the operation of removing the eye of salamander and transplanting it to another, where it has made to grow and function as a normal eye. This has, in fact, been carried out four times on the same adult the eye remaining normal at the end of the process. So as is known, this is the first time that such an operation been carried out, and it has enabled Dr. Stone to make most accurate observation of the regeneration of the of the optic nerve. The importance of this advance great, and suggests some promise of a time when such operation may be possible in a more highly dev animal.

Anatomy and Ballet (London: A. & C. Black. 194 Pp. 77. 12*s.* 6*d.*).—This unusual little handbook, written teachers of ballet—especially young and inexperienced teachers—is by a fully qualified physiotherapist who has trained in ballet technique. Miss Celia Sparger, who is sulting physiotherapist to the Sadlers Wells School, analysed the muscle and joint movements used by danc and studied the damage that may be done, especially children, by faulty movements. The chapters on th subjects are impressive. She notes the harm the growing fo may suffer through *pointe* work begun too early. The chi who "took the audience of admiring relatives and friends by storm" may, as a young woman, be unable to find shoes fit the enlarged toe joints "which appeared long after she h forgotten all about the clapping." The fact that ma painful disabilities of middle-aged feet begin in childhood only just gaining recognition[1]; and the late results are se not by the child's mother or his dancing teacher but by th doctor and physiotherapist who have to do what they can a permanently disabled foot. The anatomy in Miss Sparger book is sound, but taken at breathless speed; and the spin in particular could have been described and illustrated with more detail. Good photographs and radiograms illustrate the text, supplemented by the clever diagrams of Mr. Eric M Agnew. If Miss Sparger reaches her audience successfully she will prevent some disabilities in a coming generation. The great teachers, as she says in her preface, need no textbook: they have a profound understanding of the movements of the body, sharpened by constant observation. Yet even they may welcome this informative little work on the actual mechanisms of movement; for, as Miss Ninette de Valois says in an introduction, "observation has a habit of sometimes turning into a long-sustained question mark."

The Army's Needs

he four years since the war the Army Medical es have held their own remarkably well: for omplement of Regular officers is almost full. t the end of this year the total strength of al officers is likely to be within 10% of establish- The ratio of Army doctors to population at including soldiers' families, some Colonial troops. d labour forces. and civilians (notably in the ol Commission)—is about 1·50–1·75 to 1000. conscription to end. this ratio would fall sharply,) less than half the doctors now serving have d the Army under the National Service Act. ven with continuing conscription the position is to become slightly less satisfactory. since forward more and more of the men who qualify lready have completed their military service in ray or another. As things stand, however, the hief cause of concern is not numbers but distri- n. The terms of the National Service Act apply octors only up to the age of 30: and those ited in this way are a negligible source of special- ill. For specialists, therefore, the Army looks largely to the holders of short-service commis- : and by the end of this year these are expected no less than 65% below establishment.

rhaps the main task of the Army Medical rtment in peace-time is to build up a body dministrators capable of handling the corps mushroom war-time growth: in the late erstwhile civilian doctors were able to play a and useful part in the Army because they backed by able Service administrators. But the rtment also has to provide efficiently for the care of serving soldiers, and it must therefore means of making good its deficiency of specialists. this end any of three courses may be pursued: ly steps may be taken to enhance the attraction ervice life; secondly. civilians may be invited ork alongside Service doctors for a prescribed od: and thirdly, by liaison with the National lth Service. civilian doctors may be seconded to Army. At present the first two courses are being owed. In trying to increase the appeal of Service the important factors to be weighed are clinical ources, family accommodation, and pay. Clinical ources are certainly improving, thanks to closer er-Service integration; in several large overseas stations shared by the three Services. medical responsibility has been assigned to the largest user, thus making for bigger medical units and greater clinical experience. The matter of accommodation is particularly important because about half the Army is serving overseas and an unusually high proportion of potential medical officers are married; and here the position has deteriorated. for whereas the large pre-war stations in India, Egypt, and elsewhere had adequate married quarters, the post-war dispositions concentrated on Malaya. Hong-Kong, and the Middle East commonly enforce separation of husband from wife and children. Only the third factor—pay—is what may be termed fluid. The medical "wages' policy" instituted under the National Health Service has underlined deficiencies in other fields; and the universities. research organisations, and other bodies have already attempted to adjust their scales accordingly. Will the Army follow suit? The obstacles are formidable. Within the Army the conferment of greatly preferential terms on doctors might cause much dissatisfaction among highly trained men in other arms of the Service, in much the same way as a recent advertisement for civilian surgeons to work with the Army overseas evoked expressions of disgust from Service specialists engaged at a much lower rate of pay.[1] Moreover, the concurrence of the other two Services would have to be secured; and they might take a quite different view. The Minister of Defence in turn would have to review the claim in the light of his commitment to a share in economy cuts; and finally the Cabinet would adjudicate on the claim against the background of the national financial situation. Yet, notwithstanding these impediments. there is some reason to hope that the scal will be improved. Apart from this, two further facto may soon operate in the Service's favour. The fi is that young doctors may within the next year two be more ready to consider a career in the Arn for, judging by experience after the first world the period of revulsion against military service soon be coming to an end. Secondly, when hos establishments have been finally determined and a number of would-be specialists may turn or however sadly, to the Army. The reluctance at to abandon the competition for places in life is reflected in the result of the advert already mentioned. which asked civilian work with the Army overseas for eight at the rate of £1500–1700 a year plus for allowance. Not a single suitable applican

This unresponsiveness prompts the larg whether the whole approach to the dist doctors between the civilian service and is not too narrow. Were it arranged fo seconded to the Forces for a time wit status in the National Health Service. t tion to go overseas would be largely furthermore, the three medical services were united and were associated wit Medical Service, the promise of cli might be so rich that the chance eagerly seized. At the end of the wa hopes of unification[2]; but so far

Menopausal Syndrome

Estigyn enables the symptoms of the menopause, due to decline in the œstrogen secretion of the ovary, to be effectively treated by specific replacement therapy.

Estigyn is a highly potent œstrogen derived from natural sources and is active orally. In addition it is non-toxic in therapeutic doses. The improvement in subjective symptoms and the restoration to normal outlook is, in many cases, gratifyingly rapid while at the same time the possible onset of pruritus vulvæ or kraurosis vulvæ is prevented.

,se—so-called abortive treatment. Such treat-
was likely to be irregular, haphazard, and
icient; there would be no proper follow-up;
he patient would be indifferent and uncoöpera-
or else seriously overanxious because of the
tainty about infection. In a long experience
el HARRISON had yet to see a case in which the
and-see policy had been disastrous. The argu-
that treatment without diagnosis was bēneficial
public health was equally unsound: the under-
d patient was always a danger, for, though
ce lesions might clear or be suppressed, the risk
fection through the seminal fluid, the placenta,
he menstrual fluid remained. Adequate observa-
and tests of cure were essential in all cases,
ver treated, and it was probably a sound rule
penicillin should not be used for the treatment
nereal disease unless a sure diagnosis had first
made.

the discussion which followed most speakers
d with these views, though some adopted the
of "devil's advocate." Dr. ROBERT LEES, the
lent, thought some latitude must be allowed
there are no laboratory facilities—e.g., with
en at sea and in certain undeveloped countries where venereal diseases are very prevalent. Other exceptions to the rule, which seemed to be generally acceptable, were the case in which a pregnant woman has been exposed to syphilitic infection shortly before term, and the one where the appearances are typically those of gonorrhœa but the gonococcus cannot be found. On the subject of oral penicillin for the treatment of venereal diseases, strong views were expressed and it was even suggested that such treatment should be condemned as a public danger. Reference was also made to the medicolegal difficulties which may arise through abortive treatment or treatment of symptoms and signs without proper diagnosis. The venereologist is unhappily often involved in problems which reach the divorce-court, and the question arises whether the claims of justice can be satisfied on the testimony of a doctor who has given treatment after a risk of infection or because symptoms and signs resembled those of venereal disease.

The evidence and the weight of expert opinion is thus on the side of first principles. "Diagnosis before treatment" is not just one of the quaint sayings of the past, and to disregard it is to incur a serious responsibility which should be accepted only in exceptional circumstances.

Annotations

THE QUEEN IN QUEEN ANNE STREET

FENTEEN years ago, when the Royal College of
tricians and Gynæcologists was only three years
ad was struggling for survival, it received encourage-
from the Queen, who, as Duchess of York, became
st patron. Her Majesty's interest has been main-
d, and at a meeting of the college at 58, Queen
Street, on Nov. 3 she was presented for the honorary
ship by Sir William Fletcher Shaw, a past president,
asked her admission "for all she has done for the
it of British womanhood, for the great example
as given us of domestic happiness, and for her con-
support of this college." Prof. R. W. Johnstone,
r fellow in Scotland, joining in the presenta-
as a fellow countryman, referred to the Queen's
peutic powers: when she visited a hospital she
ited every patient in it—"which is more than any
s can do." Sir William Gilliatt, the president,
g admitted Her Majesty, spoke of her direct help
e college and her indirect help to mothers and
ren through her moral influence. In her reply the
n said: "I share with all my heart your belief
it is on the happiness of home and family life that
rue worth *and strength of a nation depend.*"

e graceful ceremonies ended with the installing of
Hilda Lloyd as the first woman president of one
r Royal Colleges, and of Mr. V. B. Green-Armytage
Mr. J. Eric Stacey as vice-presidents. Then the
n, wearing her new gown of black bordered with blue
silver, took tea with some of the members of the
cil, and inspected the charming but diminutive
ises of the college, to whose general fund she
y made a generous gift.

CLOTHING MAPS

NE of the many urgent questions raised by the late
was how to clothe men who were to be transported
their familiar climate to one of which they, and
those responsible for them, had no experience.
as not enough to issue ducks and topees for the
ics and wool and fur for the Arctic, though such
sures may have sufficed in the more leisurely past, when loss of efficiency was accepted with equanimity. Global warfare demanded *Clothing for Global Man*[1]; as Professor Lee of Johns Hopkins and Dr. Lemons of the U.S. Quartermaster-General's Office put it. Empirical and individual information had to be coördinated and some universal scientific law established from which the clothing requirements for a given situation could be predicted provided some critical physical characteristics of the situation were known. To this end were bent the energies of physicists, physiologists, textile technologists, and geographers. The result of their labours was new maps of the continents, based not on changing national boundaries but on variations in the mean temperature, dividing the earth into eight clothing-allowance and climate zones.

In making the maps many factors had to be taken into account, of which temperature and humidity were the most obvious, followed by wind chill, radiant energy, dust, rain, precipitation, altitude, glare, noxious fauna and flora of all kinds, and so on. The men to be clothed would sometimes be at rest, sometimes working to the limit of their capacity. Incompatibles had to be combined somehow, so that in hot climates the men could keep cool and yet be protected from insects and plants, and in cold climates could keep warm and yet be unimpeded in movement. Both textiles and tailoring were carefully studied; materials had to allow evaporation and yet not retain so much moisture that chilling would occur; clothes must fit well enough for physical and mental comfort and yet not be so close that useful insulating air was expelled from between garments. The standard clothing outfit was taken as that which would maintain thermal equilibrium when the man was "standing around or performing very light tasks" (an hourly expenditure of about 75–90 cal./sq.m./hr). For increased activity garments must be removed and for decreased activity added. Garment units or layers were devised, one garment approximating half a layer, and a standard layer being about $^1/_4$ inch thickness of clothing over the entire body and such that it gave adequate environmental protection, under the conditions prescribed, for each range of temperature of 18°F. Finally, clothing almanacs were compiled which showed by the there was much less difference in antibody content between the cells and the plasma. From this they inferred that lymphocytes could readily part with their antibody; on the other hand, further experiments showed that lymphocytes did not take up antibody when incubated in plasma rich in it.

---

[1] Lee, D. H. K., Lemons, H. *Geograph. Rev.* 1949, 39, 181.

On general grounds, antibody formation might be regarded as a form of secretion—a process which usually requires a cell with a fair quantity of cytoplasm. But the small lymphocyte possesses very little cytoplasm, and by analogy with other secretory cells would not appear to be structurally suited for antibody formation. It is all the more interesting, then, that the view has been gaining ground that a cell with rather more cytoplasm, the plasma cell, is the chief source of antibody. Last year, FAGRAEUS[17] reported that the administration of antigens was a powerful stimulus to the multiplication of plasma cells, which in turn were derived from reticulum cells. This was particularly noticeable in the splenic pulp, where first of all large numbers of immature plasma cells appeared, and then as the titre curve of antibody levelled off these became transformed into mature plasma cells. In-vitro studies of splenic tissue showed that very much more antibody was present in the red pulp than in the lymphoid follicles, while the capacity of the red pulp to form antibodies seemed to be directly related to its content of immature plasma cells. A correlation was also established between the formation of antibody globulin and histochemichal changes in the plasma cells—namely, cytoplasmic basophilia and increased ribonucleotides. It is worth noting in this connexion that DOUGHERTY and WHITE[8] had reported an increased formation of immature plasma cells in the lymphoid tissue of rabbits within a few hours after the injection of cortical hormones. At the same time they had observed increased basophilia in the cytoplasm of many of the smaller lymphocytes, which on superficial examination apparently resembled plasma cells. Lately, EHRICH and others,[18] studying the cellular changes in the popliteal lymph-gland after injection of typhoid bacilli into the pad of the foot, found that the period of maximal antibody formation at 4–6 days after the injection was associated with an increase in ribonucleic acid in the cells. The cellular reaction at this time was mainly of plasma cells, which they decided were formed from specific plasmoblasts and not from lymphocytes. They finally concluded that it was the plasma cell and not the lymphocyte which was responsible for antibody formation. HARRIS and HARRIS,[19] however, performed similar experiments—again in rabbits, but using different antigens (dysentery bacilli, influenza irus, sheep erythrocytes)—and reported an increase, ot of plasma cells but of lymphocytes rich in riboucleic acid. It is difficult to reconcile their experients with those of EHRICH and his colleagues, unless e assumes a differential response of the lymphocyte different antigens. It seems clear too that the er histochemical methods are reviving the old troversy concerning the origin of plasma cells— they formed from lymphocytes, or from a specific ursor, the plasmoblast?

Abortive Treatment of Venereal

THE aphorism "diagnosis before treatment" a fundamental principle of medical practice on all sound teachers have laid stress. Does this ciple admit of exceptions? Are there circumstances, affecting the patient or the health, which justify treatment for disease may not be present? It has been widel with some dissentients, that the venereal exceptions, and that some forms of treatment are desirable where patients have endangered by promiscuous intercourse[1] tration of effective antibiotics is so easy and safe practitioners must be sorely tempted to give patients who are worried and distressed. et al.[2] and PLOTKE et al.[3] have shown incidence of early syphilis among people sexually to infectious early syphilis can be diminished by single injections of 0·6–0·9 of procaine penicillin; and this experimental has so convinced medical opinion in the U that abortive treatment for syphilis is now practice there.

When the pros and cons of abortive treatment discussed by the Medical Society for the Venereal Diseases on Oct. 29, Colonel L. W. spoke of the increase of "sulphonamide gonorrhœa during the war, when sulph became available for self-treatment, through agency of seamen and Allies, and were given in therapeutic doses by many practitioners. The wholesale and haphazard use of penicillin filled him fear for the future, and he thought the use of by mouth for prophylaxis was particularly because of irregular absorption, haphazard dosage half-hearted treatment. The prevailing practice of ing, without proper diagnosis, lesions and which might or might not be due to syp gonorrhœa was to be condemned: after such ment correct diagnosis was either impossible or delayed: and the resulting uncertainty was disastrous to the patient's state of mind, making a candidate for syphilophobia. If the tre appeared to be successful it was likely that patient would never be seen by a specialist and have no proper observation and tests after Colonel HARRISON referred to the obvious masking the effects of early syphilis and the bility that the incidence of late serious manifest affecting the central nervous and vascular systems increase. With older remedies, such as the it had been shown that under-treatment was to increase the risk of neurological mani syphilis; and though many had claimed the forms of relapse which affected the nervo system were rare after treatment with penicillin was still too early to accept this conclusion and end-results remained to be determined. All the arguments against the treatment for symptoms and signs without accurate diagnosis applied equally, Colonel HARRISON's opinion, to treatment of pe who had taken a risk but had no manifestations

; gave high titres of serum-neutralisation in eggs, and 20 pairs of sera showed a fourfold or greater rise in ıæmagglutination properties to N.D.V. during the se of convalescence. In contrast, only 3 of the control gave high titres of neutralisation to N.D.V. and none 'ed a rise in antihæmagglutinating factors against virus. In the 5 cases of meningo-encephalitis where spinal fluid was examined for N.D.V. the virus could be isolated.

ıese results are against the view that Newcastle ıse virus is widely concerned in human disease. logical results with this virus obviously require ious interpretation, and apparent neutralisation of virus in vitro may be due to some property of the n other than specific antiviral antibody. Another bility is that mumps and N.D.V. share some common gen, and several years ago Burnet and his associates [7] hasised the biological closeness of N.D.V. to mumps the influenza viruses in virtue of the effects of their ral agglutinins on human red cells. It is clear that infections will often be very difficult to differentiate s the actual viruses can be isolated.

STANDARD HOSPITAL COTS

ɪᴇ British Standards Institution have drawn up a dard specification for children's cots in hospitals. differs from what is customary chiefly in that the es between the vertical bars, or "filling tubes," are ced to 3 in. (or 3$^{1}/_{4}$ in. in specially wide cots). Most ıe present cots have a spacing of 4 in., which until has seemed reasonably safe; but many have a wider of 4$^{1}/_{2}$–5 in. at each corner, where one of the bars ent at a right-angle to form a stop that limits the award movement of the dropside. It was in such a hat a baby fatally dislocated his neck by squeezing etween the bars some months ago.[8] When the new are in use, the elimination of the potentially dan- us gap and the closer spacing should make this icular accident impossible, and in the meantime ital management committees will no doubt act the Minister's request to reconstruct any of the style cots they have in their wards.

vo years ago Napier [9] pointed out that the dropside often unnecessary, and he contended that its removal e for safety, reduction of noise, and the conservation urses' time and energy. He favoured a fixed side e 6 in. high for babies who are beginning to sit up would therefore be unsafe in an open cot. In line this argument, the B.S.I. proposes that, where an rmediate position for the dropsides is required, extra ets to support them shall be fitted 10 in. above the l of the wire mattress. This halfway position is to commended, for in suitable cases it will allow most sing procedures to be done without moving the side. But often it will still be necessary to raise lower the sides of cots to their full extent, and ier showed that in this way the nurses in a single d may have to lift nearly a ton of metal in 24 hours. seems to be a good reason for making dropsides of e light alloy instead of steel; and it would make for ce and quiet in hospital wards if rubber facings e attached wherever metal comes against metal. ses will rejoice that in the new cots the dropside go right down and swing inwards when lowered. things are it often does neither, and gets in the way he nurse's feet as well as her hands during bedmaking. type of safety-catch to be fitted is not specified. ingenuity of manufacturers will be taxed in devising atch easily and quickly released by the nurse and proof against the young patient's urge to undo it.

THE CHARGE FOR PRESCRIPTIONS

DESPITE growing opposition the Government have apparently decided to proceed with their plan for charging up to a shilling for National Health Service prescriptions. The question is whether this charge will really achieve any material saving of money or of professional time. Some hold that the time it does save will be won at the cost of discouraging early resort to medical advice. Thus the council of the Pharmaceutical Society have told the Prime Minister that—on the basis of pharmacists' experience in dispensing National Health Service prescriptions—they are satisfied that the charge will not deter those who are misusing the service to a serious extent. They think that "the charge will be prejudicial to the use of the service by persons who need medical attention but will not reduce excessive and unnecessary resort to doctors and chemists by those who are least deserving of the benefits they are receiving." On the other hand, this may well be an unduly pessimistic view; and the Government, accused of timidity in their economy measures, will naturally be unwilling to drop one which in principle enjoys a good deal of support.

The only group for whom the Prime Minister suggested a special exception were the old-age pensioners. Since his statement similar special consideration has been claimed for many other groups, including children, students, widows, and those who are ill for a long time. The exemption of these groups would not be impossible, though it would present varying degrees of administrative difficulty. Actually it is the difficulty of collecting the tax that is now so widely pleaded as a reason for its abandonment. No more can usefully be said until we hear the Government's proposals in detail.

EDUCATION FOR HEALTH

Lord Woolton welcomed representatives from many countries and professions to the two-day conference which the Central Council for Health Education held in London this week. He gave "a public buzz to a bee that is constantly in my bonnet" in an adroit and convincing plea for instruction of the ordinary man in what he should eat to keep healthy. Prof. W. O. Lester Smith asked for closer liaison between education and health services. Prof. Andrew Topping, F.R.C.P., declared that we must debunk the idea, for which doctors bear a share of the blame, that the less the layman knows about the causes of disease the better for his peace of mind. Frank discussion with inquiring patients was more time-consuming than an arbitrary diagnosis and a scribbled prescription, but the latter did nothing to help the patient to avoid sinning against the rules of health. Dr. Topping deplored the prudery which hindered effective publicity on the mode of spread of food-poisoning; even if in her day Queen Anne was not admitted to have legs, surely it was now realised that everyone had a large bowel. Dr. Melville Mackenzie said that we had much to give and also much to receive in matters of health education; he emphasised the value of international organisations, and especially W.H.O. Prof. R. H. Parry held that the ordinary man, who wanted to know how to look after "his only real estate—his own body and mind," needed a sound knowledge of elementary biology, the capabilities of his own body, and how to use his own reason, with an occasional word of advice on personal problems. An exhibition of films, filmstrips, and models was held in connexion with the meeting.

Sir HORACE EVANS, K.C.V.O., F.R.C.P., and Dr. DANIEL T. DAVIES, C.V.O., F.R.C.P., have been appointed physicians to the King.

Dr. O. C. CARTER has been elected to the General Medical Council as a direct representative for England.

use of double-entry tables, item by item and month by month, the clothing requirements of a specific "clothing almanac region." Psychology was not forgotten and social customs and fashions were taken into account.

Many difficulties faced the investigators, from the entire absence of scientific data for some parts of the world, and inadequate data for others, to the problem of reducing to mathematical terms the effect of clothing on heat-loss from a body as awkwardly shaped as man. They seem to have achieved a great deal in a new field, though much remains to be done. We have come a long way from the belief that only a woollen cummerbund can stave off death in the tropics.

"CONVERGING PROGRESS" IN WESTERN UNION

ON Oct. 29 we described the efforts now being made to bring the social services of the Western Union countries into closer relation with one another. The five Powers of the Brussels Treaty (France, Belgium, Luxembourg, the Netherlands, and the United Kingdom) are negotiating bilateral agreements which will link their social-security schemes into a network covering such benefits as those provided for sickness, invalidity, old age, death, maternity, industrial injuries, and prescribed occupational diseases, for their nationals, no matter in which of the countries they may be living, or have lived. The five Powers have now signed a multilateral convention, which will enable a national of any of the five countries to benefit from any of these bilateral agreements. A second convention, also signed, is based on the principle that if a national of any of the five countries, when resident in the territory of any of the other four, needs social or medical assistance, but is without sufficient resources, he shall receive such assistance from the latter country on the same basis as its own nationals. For example, an Englishman living in Holland, who is without sufficient resources, will receive the same free hospital treatment as a Dutchman in similar circumstances; or a Frenchman, living in Belgium, who is too old to earn his keep, will receive the same assistance as a Belgian in the same situation. The five countries will not reimburse each other for the cost of such assistance.

Repatriation solely on the ground that assistance is likely to be long-continued or costly is not to be resorted to if the person concerned has, for instance, close family ties in the foreign country in which he is living or has resided there for more than five years (ten years if he entered that country after the age of 55) or is not in a fit state to be transported.

THE SMALLER HOSPITAL

REORGANISATION is a thankless task for the reorganisers; while to the reorganised it is generally anathema. It would be irresponsible, in those who have no first-hand experience of the difficulties, to protest at every step the regional hospital boards take in their efforts to rationalise the hospital services; but it would be equally wrong to withhold criticism when some important principle seems to be set aside. This week two of our correspondents put the arguments for maintaining the identity of the smaller hospitals: Mr. Michael Harmer for a particular case, Dr. Annis Gillie for such hospitals in general.

When a service is adequately covered by the large hospitals of an area, it must be exceedingly tempting to revise the purpose of smaller hospitals which duplicate it. But, quite apart from possible destruction of valuable traditions, can we be sure that action of this kind is on the right line of evolution? There are several authorities on hospital development, who believe that in course of time we shall see a return to small hospitals, for the very reason which Dr. Gillie outlines. It matters to the patient, if to nobody else, that should be seen by the same doctor each time he Dr. J. M. Lipscomb[1] has well described the fate of patient bandied between consultants, first assi a dissolving panorama of house-physicians, until began as an innocent and easily removable becomes a malignant neurosis with secondaries where. In the small hospital continuous care by doctor, or a small group of doctors, is the rule the exception; whereas in the large general hospital is the exception rather than the rule. It is also to the patient to meet the same outpatient sister same small band of fellow patients; it is even to become known to the same hospital porter. T things make for the security on which recovery health so often depend. Moreover there are questi time and distance: the small hospital round the is used more willingly than the large one a bus away.

Is it too late for hospital boards to reconsider policy? Is it not possible that they are moving in wrong direction? It may well be wise to equipment in large centres; but does this oblige us concentrate people too?

NEWCASTLE VIRUS DISEASE IN MAN

THE virus of a common disease of domestic first isolated in 1927 by Doyle in Newcastle and known as Newcastle disease, has until lately regarded as an uncommon human pathogen. before 1948 the only known examples of human infe were sporadic cases of conjunctivitis either in labo workers or in people handling poultry; in further of this kind reported in the U.S.A. this year,[2,3] virus has been recovered from washings or from the conjunctiva. But in 1948 Howitt and investigating a febrile disorder accompanied by encephalitis, occurring in epidemic fashion in Te and Alabama, found that the convalescent sera from patients neutralised Newcastle disease virus (N.D.V.) a high titre when mixtures of virus and serum inoculated into fertile hens' eggs. They concluded widespread infection by the fowl virus did occur at in man, though they did not prove their point by rec ing virus from human specimens, nor did the picture of their cases resemble that previously recorded in laboratory infections of the eye by the virus. by this report, Jungherr and others[5] have investi similar cases of a mild meningo-encephalitis, and have also studied serum samples from mumps pa Unexpectedly, the convalescent mumps sera were ones which neutralised N.D.V. strongly, whereas the from the meningo-encephalitis cases had either a or no neutralising capacity for this virus. In a report[6] these workers give more detail of this inv tion. Sera from 22 cases of clinically typical yielding mumps virus in 11 instances by direct test, examined with both mumps and N.D.V. anti Complement-fixation and agglutination-inhibition showed the expected rises in antibody to mumps during convalescence. Sera from 14 control cases meningo-encephalitis and from 7 cases of nonparalyti poliomyelitis did not show evidence of mumps infectio by the agglutination-inhibition or complement-fixatio tests. When examined against N.D.V., 13 of the 22 mump

absent from school on May 25, 27, and 28 with a ned ankle.

ough the relations between the R. and N. families again described by both parties as unfriendly, fresh ry revealed that the school-girl E.N. often acted "baby-sitter" while Mr. and Mrs. R. went to the na, and that she was accustomed on such occasions ed the baby (B.R.)—without, however, changing apkins. Her parents were uncoöperative during the quent investigations, which revealed that the er (Mrs. N.) and another child (M.N.) were infected S. *paratyphi B*. Both had been quite symptomless remained so after their admission to hospital on 5 and 7. Mrs. N. was breast-feeding an eight-h-old baby, who was permitted to accompany o hospital and remained uninfected throughout its there.

further cases of paratyphoid infection were vered after these.

CLINICAL COURSE

the 13 persons involved, 3 adults (Mrs. R., Mrs. S., Y.) had severe attacks of paratyphoid, with fever g 23, 24, and 19 days from the onset. One of these R.) said she had been inoculated with T.A.B. ally from 1941 to 1944 during service in the A.T.S. reference to her Army pay-book confirmed this. was three months pregnant and during her illness spontaneous and complete abortion. None of the s had ever had T.A.B., except possibly Mr. M. during ce in France in 1914–18. One adult had a mild attack very little toxæmia, and 2 children had short sharp ks of diarrhœa, lasting for two and seven days.

e remaining 7 persons (3 adults, 4 children) did not t sick at any time. One of these (E.N.) was the only in the series from whom the organism was not ted. Her serum agglutinated paratyphoid B(H) en only and to the following titres: 1/320 on 3; 1/50 on June 17; and 1/125 on June 21. These ngs support the view that she had been recently ted. She had never had T.A.B. inoculations. A later her stools and urine are still repeatedly tive, but her Widal for paratyphoid B(H) is positive).

ere were no deaths. Of the 3 patients who were ely ill 2 had signs of myocardial weakness but made d recovery, and all were quite well a year later.

CLEARANCE OF INFECTION

e standard adopted for release from isolation was gative result from six consecutive specimens of and urine taken half-weekly. As already stated, *ratyphi B* was never recovered from 1 of the hospital nts. Of the other 9, 8 ceased to excrete the aisms after periods varying from six to forty days, so did the 2 children who were isolated at home.

e man who was not admitted to hospital (Mr. R.) in another town, and after the initial positive urine t on April 23, only one further report was available—s and urine both negative on May 21. His blood ed the same agglutination findings on May 12 and 26—namely, paratyphoid B(H) positive 1/50. We anxious about him because it was difficult to imagine taking appropriate care to prevent spread; but no her cases have been attributed to him.

PERSISTENT CARRIER STATE

he remaining case (Mrs. N.), who had no symptoms, inued to excrete *S. paratyphi B* in both fæces and e during the sixteen weeks she spent in hospital. was breast-feeding a healthy infant throughout and child did not become infected nor has it done so since. ear later, Mrs. N. is still a persistent fæcal and urinary carrier. Another one of her children has recently (September, 1949) been found to be infected (fæces positive for phage-type IIIA and Widal paratyphoid B(H) 1/450) without having had any sign of illness. Incidentally in June, 1949, this child's fæces contained *S. typhi-murium*.

EPIDEMIOLOGY

We thought at first that the 5 earliest cases discovered had their origin in Mr. R. (senior), who had apparently been quite well but was excreting *S. paratyphi B* in his urine. He had lived alone in the district for many years, but his son had only recently set up house with his wife and child near his father. For the first time in recent years the grandfather had the opportunity of visiting them *frequently*, bringing various delicacies for the baby. The old man may have been the starting-point of the series, but we have no evidence to show whether he remained a carrier subsequently.

The middle-aged man (Mr. M.) rapidly became a non-excreter of the organism and it is improbable that he was a carrier. He was almost certainly infected by one of the R. family.

When the school cook was found to be infected we could not, by any analysis of evidence—contact, food, food-suppliers—link her with the R. family. We thought it most unlikely that two independent foci of infection (by organisms of the same phage type) should appear almost simultaneously, but we could not trace the connexion between them.

Notification of the schoolgirl E.Y. was regarded at the time as the prelude to a major outbreak. We thought she would prove to be one of many infected by the cook. However, time passed without bringing any further cases. It was the repeated questioning of E.Y. that eventually revealed a connexion with the original house through her classmate E.N. We realised that we had been deceived in regard to the relation between the two families there, and had not been sufficiently alive to the need for bacteriological and serological testing of the family in the upper flat. We now believe the mother of this family (Mrs. N.) to have been the origin of the series. She is the only proved "carrier" in the series. She is a chronic carrier now and probably was then. (It is true that she had worked in canteens off and on until rather more than a year previously without any cases of paratyphoid having been attributed to her.) We suppose her daughter (E.N.) to have been infected by her and to have passed the infection to the first case in family R., to the first case in family Y., and possibly even to the cook.

It is most improbable that the cook, if she infected anyone through the school meals, would have infected only 2 out of 260 pupils. At this school, girls in the senior forms were permitted to visit the kitchen on various errands, but junior girls (such as E.Y. and E.N.) had very little opportunity for doing so. In spite of this it is suggested that somehow the infection reached the cook from E.N. This theory is the one that most nearly fits the facts, even if it does postulate, for the spread of infection between diner and cook, a reversal of the more usual direction.

We have not discussed the various administrative measures involved, such as correspondence with doctors and action under the Public Health (Infectious Diseases) Regulations, 1927, because it is the chain of infection we regard as chiefly interesting, and also the absence of symptoms in 7 out of 13 persons involved. We think that, besides bacteriological investigation, repeated Widal examinations would have been useful for distinguishing the chronic carriers from recent symptomless infection. We recognise that, had we perhaps been a little more prescient, case E.N. might never have caused infection in the later cases as we believe she did.

Public Health

A SMALL OUTBREAK OF PARATYPHOID FEVER

E. D. Irvine
M.D. Lpool, D.P.H.
MEDICAL OFFICER OF HEALTH

T. G. Galvin
B.Sc., M.B. N.U.I., D.P.H.
DEPUTY MEDICAL OFFICER OF HEALTH

DEWSBURY

After several years' freedom from paratyphoid, Dewsbury, a town of some 52,000 inhabitants and the centre of the heavy woollen district, experienced a small outbreak in the second quarter of 1948. Of the 13 persons known to be affected, 12 resided in the town and 1 in an adjoining borough. In 12 cases *Salmonella paratyphi B* was isolated from one or more of three sources—blood, fæces, or urine. In the 13th case the diagnosis was based on positive Widal reactions. The organism was proved in 11 cases to belong to phage-type IIIA, but in the other case was unfortunately not typed.

SEQUENCE OF EVENTS

The first 3 cases, notified on April 16, were those of a boy aged sixteen months and his parents in their middle twenties. The child (B.R.) had had diarrhœa for a week from March 30 but had recovered. The father (Mr. R. junior) had had symptoms beginning a week after those of the baby; and four days later the mother (Mrs. R.) had sickened with diarrhœa and headache, a severe classical attack of paratyphoid ensuing. The 3 cases were notified when the family doctor learned that *S. paratyphi B* had been isolated from fæces taken from the mother on April 12.

On visiting the family's basement flat it was found to be empty. The mother, who was really ill, had been removed by taxi two days previously to her father's house ten miles away, where another doctor had been consulted and had sent her into a general hospital, as a suspect enteric case, on April 16, the very day on which she was notified in Dewsbury. She was transferred to Dewsbury Isolation Hospital that evening. The father (Mr. R. junior) and baby (B.R.) were traced to another part of Dewsbury, where they were staying with some friends, a middle-aged childless couple, and were forthwith removed to hospital. Their hosts, Mr. and Mrs. M., were both well, but Mr. M. was found to be infected (fæces positive) and he was admitted to hospital on April 21.

The baby's paternal grandfather (Mr. R. senior), who lived in an adjoining borough, was also found to be infected. He appeared to be quite well, but *S. paratyphi B* was isolated from his urine taken on April 23, the fæces being negative. Unfortunately this (his only positive) sample was not phage-typed. He had no symptoms and was not admitted to hospital. He was not helpful, and it proved impossible to get a connected story from him.

Routine inquiries showed that in the same house as the original cases there was another family (N.), all of whom were well, living in the ground-floor flat with a separate water-closet. There was a communicating door between the two parts of the house, but the two families were said to be unfriendly and not on visiting terms.

So far, all 5 persons known to be infected were close contacts of one another. Mrs. R. left her child to be minded, during working hours, by Mrs. M., who provided them both with a midday meal, and quite regularly had Mr. R. junior as a visitor. Mr. R. senior frequently visited his son's home, bringing sweets and cakes for his grandchild, and was in turn visited by them. A careful investigation was made of food eaten and of food-suppliers concerned; but the only interesting finding was of *S. anatum* in dried egg consumed by family.

EXTENSION OF OUTBREAK

At this stage it was hoped that the outbreak remain confined to the family circle of these 5 but on May 1 a fresh case was notified. The (Mrs. S.) who lived in an entirely different part of bury, had been admitted to a local general hospital days before and was now transferred to the isolation pital on a clinical diagnosis of paratyphoid, confirmed. She had not appeared well since and had complained of headache on the 21st; had continued to work until the afternoon of the Some anxiety was felt when her occupation was closed, for she was the cook at a day school for attended by some 320 pupils, of whom 80% took at school. Fortunately she had a high standard of hygiene, and also did not suffer from diarrhœa two days after she stopped working.

SCHOOL CONTACTS

For the next few weeks everybody attending was supervised by the staff of the health department. absentees and those complaining of any form of during the period beginning on April 12 were up—at first daily, and later at short intervals—and was continued until July 14. Bacteriological tions were made in all cases of illness which were remotely suggestive of enteric. We decided offer mass T.A.B. inoculation to the school-children staff, because in theory the first crop of secondary was already imminent. Some children, however, inoculated by their own doctors, who had been informed of the course of events.

A surprisingly large number of the children transient headache and diarrhœa, and 35 children 5 staff were investigated bacteriologically. these, 3 cases of salmonella infection were dis (1 of *S. enteritidis*, 1 of *S. typhi-murium*, and *S. paratyphi B*).

About this time cases of paratyphoid were reported Horbury, a neighbouring sanitary district. As one cases had associations with that town we were end to trace any connexion, when Dr. W. G. Evans informed us that his cases belonged to phage-type I, proved that the two series were unconnected.

FURTHER CASES

The child at the school who was found to harbouring *S. paratyphi B* was a girl of 13 (E.Y.). W admitted to hospital on a bacteriological finding (fæ positive) on May 12 she was quite well, but had been under her own doctor's care for a attack of diarrhœa which started on May 1 cleared up in two days. When her home was visi arrange for her admission to hospital, her father (was found to be in bed suffering from "lumba He was admitted to hospital at once with a c diagnosis of paratyphoid, later confirmed.

Further investigation of this family revealed 2 other children, M.Y. aged five and A.Y. aged were infected (fæces positive); but they had had symptoms, and they did not become ill. They isolated at home under strict supervision.

At this stage T.A.B. inoculation was offered to one in the school, and 77 persons were inoculated

Almost casually, after E.Y. had been in hospital weeks, she revealed that she had been given "sh powder by a classmate (E.N.), who was one of family of 6 living in flat above the original Accordingly the N. family was at once reconsi The child (E.N.) was found to have a positive Widal was admitted to hospital on June 4. She was and denied having had any symptoms, though she kerby. As was to be expected from so eminent oup, the questions to the speakers were very much ie point. There seems to be general agreement that meeting has done much to dispel some of the ls of misunderstanding circulating around the onal Health Service. Even the disagreements between British speakers were valuable to the huge and deeply ested American audience.

ie wide interests of the American Public Health ciation are well shown by the distribution of the ter awards for 1949. They include a special award r. Haven Emerson "for developing a programme for plete local health service in every area of the United es" (this award was received with prolonged imation); to Dr. Andre Cournand, of Columbia ersity, for his contribution to the physiology of the dation in man and the diagnosis and treatment of t-disease; to Miss Marian Sheahan for distinguished ership in the field of nursing and public health: r. Max Theiler, of the Rockefeller Foundation, for xperimental work leading directly to the production wo effective vaccines against yellow fever; to Dr. iam S. Tillett and Dr. L. R. Christensen, of New University, jointly, for their discovery and purifica- of streptokinase and streptodornase: and finally, r. Edward C. Kendall and Dr. Philip S. Hench, of Mayo Clinic, for their studies on 'Cortisone.' Group rds were given to the American Academy of Pedia- in recognition of the public-health significance of its on-wide study on child-health services and pædiatric ation and to the Life Insurance Medical Research d for "initiative and support of programmes of research the main cause of death, cardiovascular disease."

he exhibits, both technical and scientific, were of standard. The latter included exhibits by Federal State health and welfare departments. The Canadian ernment exhibit featured, inter alia, the first year of a year government health programme "illustrating foundation now laid for adequate and strategic pital facilities and the nation-wide advances in lic health and professional training promoted by ernment grants." (It seems a pity that Great tain, with such constructive efforts to demonstrate, no exhibit.) Among the technical exhibits were al aids to posture known as "Posture Pete" and impy Lou"—characters not unknown in central and l government offices in Great Britain.

nce acclimatised to the magnitude of this annual eting, the observer was increasingly impressed by smoothness with which it was conducted. This largely due to the genial enthusiasm of the president, Charles F. Wilinsky, and to the competence of the cutive secretary, Dr. Reginald Atwater.

TUBERCULOSIS IN NORTHERN IRELAND

ame Dehra Parker, minister of health and local govern- nt, has lately announced in the Northern Ireland Parlia- nt that within six or eight months the Tuberculosis hority hopes to have an additional 200 beds for patients h tuberculosis, including 116 for children. The minister ed that 1381 patients with tuberculosis were undergoing pital treatment, and that the number awaiting admission 625. In suitable cases the use of sleeping shelters in the nes of patients was being encouraged.

n the annual report of the Tuberculosis Authority, the ector of tuberculosis services emphasises the importance ealth visiting:

> "The solution to the tuberculosis problem is not revealed y the stethoscope nor by shadows on an X-ray film. It lies in he homes of the people. Whatever curative drug may be dis- overed, the ultimate eradication of the disease will depend pon our ability to obtain the coöperation of the people. . . . he reception which a patient receives when first visiting a uberculosis clinic may make all the difference to that patient's uture coöperation and peace of mind. It is no light matter to ttend at the clinic for the first time and await a verdict which ay jeopardize one's whole future, not only as regards employ- ent, but as regards home life as well. From the lips of many atients one learns how much their reception by a kind and actful health visitor has helped in the struggle ahead."

Disabilities

42. POSTGASTRECTOMY (DUMPING) SYNDROME

The expression "dumping syndrome" is neither elegant nor descriptive, but I cannot think of any really appropriate name for the symptoms that a considerable proportion of people get after a partial gastrectomy.

I had my partial gastrectomy a little more than three years ago, at the age of 59. I had had a chronic gastric ulcer for three years, and, owing to pressure of work during the war years, it had been very perfunctorily treated. Finally, owing to persistent evening vomiting from a delayed gastric emptying time operation was advised and willingly accepted. About two-thirds of my stomach was removed, and a Hofmeister-Polya-Lake anastomosis was done. My convalescence was not altogether uneventful. I had collapse of both lung bases, the wound went septic, a duodenal fistula developed, and I had a thrombosis in the right calf. The abdominal incision did not finally heal until four months after the operation. However, once the coughing due to the lung condition was over and the wound was no longer acutely inflamed, convalescence was almost a pleasant rest. The only odd thing was that about three weeks after the operation, in the middle of the morning, just after taking a glass of milk, I had quite suddenly an extraordinary feeling of extreme exhaustion. This recurred three times in all while I was in hospital, always in the mid-morning after taking a glass of milk. Between sister and myself the attacks were called "flops," for want of anything more descriptive. Only much later, after many such attacks, is it possible to give a really detailed account of the rather complex sequence of sensations.[1]

The symptoms are always the same. The first thing one notices is a consciousness of the action of the heart: it isn't exactly palpitation but is a most peculiar and unpleasant sensation. In really bad attacks it feels as if the heart occupied the whole of the thorax, yet there is no throbbing in the neck vessels, and the cardiac impulse cannot be felt. The rate is only slightly increased to about 90 per minute, my average pulse-rate being about 70, and there is no irregularity. Blood-pressure remains unaltered. There is no flushing or sweating and no change in colour. Simultaneous with this symptom there is a curious sinking feeling in the abdomen, perhaps rather similar to that induced by fear, &c. Lastly, there is a feeling of extreme exhaustion, so that one is compelled to lie back and shut one's eyes, not because one wants to sleep but because it seems impossible to be actively interested in anything or to move. After a time the unpleasant cardiac sensation slowly disappears and then I feel perfectly normal, though perhaps still a little tired. The attacks may be mild and just a slight nuisance, intermediate, or severe, and in a severe one I don't think I could make myself do anything. Perhaps the whole attack, whatever its severity, lasts about half an hour from start to finish.

I had no more attacks until I was fully recovered and up and about all day, when they started again. At this time they always started after breakfast. Exercise immediately after a meal, or even just standing still, seemed to bring on an attack, and I found a short period of complete rest after every meal advisable. After a few months the attacks ceased after breakfast and would come on after some other meal. The odd thing is that, having changed their timing, the attacks tend to come on only after one meal of the day for a period, and then *quite suddenly* switch to another meal. At the moment it is the evening meal. How much or what I eat seems to make no difference to their incidence, and so far I have been unable to find any régime that will influence

---

[1] A preliminary account of my symptoms was published two years ago in a letter signed "M.D." (*Lancet*, 1947, ii, 596.)

Consideration of the Public Health (Infectious Diseases) Regulations 1927 leads us to suggest that they should be amended in at least two ways :

(1) The medical officer of health should have immediate suspensory powers in respect of *cases* and *carriers* of dysentery, typhoid, paratyphoid, and food-poisoning occupied in a trade or business concerned with the preparation or handling of food.

(2) The authority should have powers to require, until revocation of the notice, known carriers of these diseases to abstain from any occupation concerned with the preparation or handling of food or drink intended for sale for human consumption whether then engaged in such an occupation or not.

It would be interesting to know how often *known* carriers are responsible for the spread of these diseases, either explosively or insidiously.

Our thanks are due to Dr. J. C. Colbeck, late director of the Public Health Laboratory, Wakefield, and Dr. W. F. Lane, the present director, who did the bacteriological work ; to Dr. A. Felix, F.R.S., of the Central Enteric Reference Laboratory, London, who was responsible for the phage-typing of the organisms ; and to the sanitary inspectors, school nurses, health visitors, teachers, and others who took part in the investigation.

Smallpox Vaccination in Argentina

At the beginning of September, some forty cases of smallpox were reported in Argentina, mostly among immigrants. Since then, according to B.U.P., the whole population of 16 million has been vaccinated. The government ruled that vaccination certificates dated not earlier than Sept. 1 must be presented at theatre and cinema box-offices before tickets could be sold : and a similar condition was applied to the sale of railway, air, and shipping tickets.

Poliomyelitis

In the week ended Oct. 29 notifications were : poliomyelitis 347 (385), polioencephalitis 20 (29). Figures for the previous week are shown in parentheses. This is the second week in which notifications have fallen, and it is hoped that the usual seasonal decline has now definitely begun. The distribution of the disease is widespread as is shown by the following list of counties in which multiple cases were reported :

London 55 (66), Bedford 2 (3), Berkshire 3 (6), Buckingham 4 (1), Chester 10 (8), Cumberland 2 (2), Derby 2 (5), Devon 3 (0), Dorset 3 (3), Durham 2 (3), Essex 26 (32), Gloucester 9 (12), Hereford 2 (0), Hertford 9 (6), Kent 16 (26), Lancaster 32 (25), Leicester 3 (13), Lincs, Lindsey 13 (7), Middlesex 17 (19), Norfolk 5 (8), Northumberland 2 (9), Nottingham 8 (9), Oxford 2 (1), Rutland 2 (1), Somerset 11 (10), Southampton 13 (13), Stafford 3 (12), Suffolk, East 2 (1), Surrey 14 (16), Sussex, East 9 (2), Sussex, West 3 (2), Warwick 8 (9), Yorks, East Riding 2 (3), Yorks, North Riding 2 (3), Yorks, West Riding 50 (47), Glamorgan 7 (6).

AMERICAN PUBLIC HEALTH ASSOCIA

FROM A CORRESPONDENT

THE first impression of the annual meeting of American Public Health Association in New York one of unwieldiness. The programme showed principal speakers spread over 108 sessions in five day a meal too large for even the most enthusiasti and it was not until the meeting was well under way the careful organisation of the thirteen sections bec clear.

Seventy-seven years ago 10 men met for the annual meeting. When this one opened on Oct. 4500 people had registered, and a total of well 5000 have been present.

At the first general session, addresses of welcome given by the Mayor of New York City (the Hon. Will O'Dwyer), and the Commissioners of the New City and State departments of health. The Hon. Martin, minister of public health and welfare for Dominion of Canada, gave an address which mad clear that the Canadians are pressing on with s services and that plans for these are well advan Indeed, the rapid development of health-insur schemes has been one of the major topics of this meet Discussion of ways and means has almost succee consideration of the general principles and, in partic the type of administrative machine required and training of administrators loom prominently. In connexion it is interesting to note the general bewil ment of the Americans at the relegation of the Br medical officers of health to a relatively minor rôle in National Health Service. Americans find it hard to un stand that the special training in administration rece by the M.O.H. has not been found of major value, and question whether lay control may not spread thr the N.H.S. and dominate it. This is no academic prol for them, because in the rapid expansion of hospitals social services of the next few years they face adm trative problems beside which our own will ap relatively simple. Federal grants under Public 725 (the Hill Burton Act) are going to speed up hos and medical-care projects and also research in fields. The training of administrators of the right cal to deal with these new developments is there fundamental, and it is in reaching common gro on matters such as these that this annual meeting excelled.

The British representatives were few in number were given important places in the programme. Percy Stocks startled his audience with the ques "Morbidity Statistics—Do We Want Them?" National Health Service figured largely in info discussion and in two formal sessions. In a joint mee of three sections, all four principal speakers were with expert knowledge of one or more parts of the ser and the interest aroused was shown by the fact that auditorium in the Penn Top at the Hotel Statler filled and overflowing. Prof. A. L. Banks, lately of Ministry of Health, described the framework of scheme, and was followed by Dr. J. S. Collings, Australia, who has been studying general-practitic services in Great Britain and elsewhere. Dr. J. T. R Edwards, representing the British Medical Associat spoke on the medical profession and the service, Dr. J. A. Scott, deputy M.O.H. for the County of Lond concluded the main papers with one on the rôle of health officer. The discussants included Dr. Ba of the American Medical Association ; Mr. Bugl of the American Hospital Association ; Prof. H Leavell, of Harvard ; Miss Alma Haupt ; and Mr. Ph second place. Despite the indignities of being hed with nauseous drugs and the discomforts ated with the administration of subcutaneous saline Thomas has not complained. Even the cinder-tray een accepted as the inevitable alternative to a o liberty through a window no longer open. With and a certain fastidious condescension he will now with the milk, the egg-white, the fish, and the y cooked liver provided. All think the corner has turned and that it will now be only a few days he is restored to full feline vigour. There should re such patients ; perhaps in the veterinary world are.

* * *

en I first published an article the part I most ed was ordering reprints and proudly posting them my friends to show them I really had got something *Lancet*. That was early in the war, when I was paid a fifth of my present salary and was at least five richer. Now I have published a few more articles getting less enthusiastic about the reprint business. ever the article one gets quite a lot of requests prints, and when they cost as much as two shillings it is no joke giving them free to large numbers of ge doctors (mostly in America) who have dispatched d cards asking for them, or to secretaries of ican libraries who have done the same.

reduce excessive traffic in reprints, any doctor is sufficiently interested in a medical paper aut one ought to make the effort to write a nal note—it's better manners, it's more amusing he author, and it allows of a word or two mment or criticism which may be instructive rican papers please copy). Admittedly some of rinted forms are models of politeness and praise :

> would be greatly appreciative of receiving two copies ur most interesting article entitled *Struve's Terrible teral Anœmia* published in *The Lancet*, Vol. *i*, No. *6234*. *Feb. 20*. Year *1943*. Page *249* and any other reprints of lar nature.

t of what value is the sterile flattery of the printed ? I am sure that if the habit spreads (and it is common in England) we shall soon find little cards le at bookstalls thus :

Parent
ar Sibling. Thank you so much for the delightful *bedsocks*
Friend
Christmas
you gave me for my birthday. They are most *comforting*.
my wedding present
k you again. I should greatly appreciate any other gifts imilar nature.

Affectionately,
Yours Sincerely, *Arthur*.
Ever,

am not going to sign this communication because ou might think I was showing off that I had had al articles printed ; (*b*) you might think I was trying t a refund of two shillings a copy from America ;) you might write and ask me for a reprint.

* * *

less he has a sleeper, nobody, I imagine, would e to make a night journey by train ; but needs when the practice drives.

e carriage was old, which I did not mind ; it was cold and dirty, which I did. Having it to myself he first half of the journey I alternately shivered or rmed a series of ungainly pas-seuls to restore lation. At the half-way stop the carriage was ded by four young sailors whose conversation, nguished merely for its crude and repetitive obscenity, eved an all-time low. They grew tired at last, and, ng my permission for granted, put out the light. so many vast puppies they curled up to sleep. pite their discourse, their snores and grunts, and their lency to encroach on my scrap of territory with ooted feet, I did not resent them ; they warmed the e up appreciably. But, on reflection, I wonder for t particular amenities I paid a first-class fare ?

"The patient had an operation for intestimonial truction . . ."

Letters to the Editor

THE SMALLER HOSPITAL

SIR,—As a general practitioner with a practice largely made up of families, I wish to record my great distress at the closing or transformation of some smaller hospitals in and around this part of London.

In sending a patient to an outpatient department one is concerned first with the quality of the opinion and treatment to be secured, and next with obtaining this at the minimum expense to the patient in terms of fear, time, and general sense of being adrift in a big organisation. This matters most, perhaps, when dealing with children and with those whose complaint is linked with shame or agitation. In the smaller hospital there is less change of personnel as a general rule ; even the porter at the door is more likely to become a friendly acquaintance, and there is a reduced chance of trying to explain things all over again to yet another doctor. Waiting time is nearly always shorter, the waiting-hall smaller and less crowded. A sense of continuity in a long case is usually greater both for patient and practitioner. When making arrangements for children and their tired mothers, or for patients with venereal disease, I almost always choose the small individual hospital in preference to the special department of the larger one. The gratitude of the patients is very great. Now we are faced with the loss of Paddington Green, the Lock, the Royal Waterloo, and the Samaritan, and are offered in each case the already overcrowded departments in the large and almost inevitably more impersonal neighbouring hospitals.

It seems indeed that these smaller hospitals, with their excellent tradition, medical and human, are being sacrificed to some plan. The basic idea that a plan exists only to be of use to the human beings it serves is indeed obscured. The argument for these " reforms " is as always the Greatest Good of the Greatest Number ; but that number is made up of human units, whose loss is usually great in proportion to their massing.

London, W.2. ANNIS GILLIE.

SIR,—Your readers are probably familiar with the decision of the board of governors of St. Mary's Hospital to convert Paddington Green Children's Hospital to adult use and for the reason which has been given for this action—namely, the excess of children's beds in the St. Mary's group over the number recommended in the Goodenough report. They may also have read the Ministry of Health circular R.H.B. (49) 132 which, together with your leading article, (Oct. 15) encouraged many to believe that the board might reverse their decision. Unhappily, there is no sign of any change of heart.

I am therefore writing, as chairman of a committee which is composed mainly of members of the local public and which is non-political, to give publicity to this fact. It seems right that the profession should know exactly what is happening because this is certainly no academic medical dispute. In Paddington and neighbouring boroughs a great wave of spontaneous public indigation has occurred and now finds expression through the Save the Children's Hospital Committee. Twenty thousand people, mostly local, have already signed a petition, and further evidence is found in the resolution passed by the Paddington Borough Council on Nov. 1, after a special committee appointed by them had investigated the matter, deploring the decision of the St. Mary's board. It is apparent that the board of St. Mary's Hospital have failed completely to understand the depth of feeling which their action has aroused. Their explanation, that students must be properly them. There are only two things I am pretty certain about—that exertion during or immediately after a meal brings on an attack; and that eating a sweet or two or a piece of chocolate soon after a meal does the same.

Two years ago there was a sudden interest in this dumping syndrome, and it was suggested that many of the attacks were due to hypoglycæmia. The delayed ones probably are, and most gastrectomy cases have an abnormal sugar curve, as I have (see table). But this does not seem to explain symptoms immediately after a meal, nor do to my mind any of the other suggestions offered, except perhaps distension of the jejunum.[2] I do tend to bring up wind just before an attack. X-ray examination shows no delay in emptying now.

* Onset of slight attack. † Attack over.

This then is the situation $3^1/_4$ years after operation. If anything the attacks get more frequent and more severe as time passes. The really curious feature is their extraordinary variability. I had an attack, mostly rather severe, every evening last week. Yet I may go a week or even a fortnight without one; I can't even suggest any explanation for this.

There seems to be nothing I can do to diminish the frequency of these attacks and so far no treatment has been of any value, though I fancy gr. $^1/_2$ of ephedrine shortens them somewhat. I cannot say they seriously affect my enjoyment of life, though when I have a series of severe attacks I do get a bit gloomy, but they are very irksome and they definitely restrict one's activities. The main trouble is the unpredictability of the attacks, and the consequent uncertainty as to what one can and cannot undertake. One can never tackle anything involving exertion after a meal, and I hardly dare accept any social engagements or attend any professional meetings in the evening, which often mean a hurried dinner, because I do not know whether I can cope.

Two comments are perhaps worth making. The first is that I don't think the layman would for a moment connect minor attacks with his previous operation; he might well fear that they indicated some heart-disease. My second point is that gastrectomy is at times performed on cases which, judged from the pathologist's point of view, would almost certainly have recovered with adequate medical treatment. I have seen quite a number of stomachs removed in which the ulcer was obviously recent, quite small, and looked as if it ought to heal given the chance. I dare say many patients will not or cannot afford the time for really thorough medical treatment; this applied in my own case. But how much weight should the surgeon give to this syndrome when he is considering doing a gastrectomy for ulcer? No doubt, what with the continual vomiting and my age, I was bound to have a gastrectomy; and the attacks, with all their unpleasantness, are I think, preferable to vomiting every night. But if I had known that I was going to be in for these attacks and had had just a gastric ulcer with its accompanying pain I would rather have put up with that.

In England Now

A Running Commentary by Peripatetic Co

RANCID cod-liver oil. Sounds bad and smells How well I recall the intolerable stench of Dr. compound fracture ward in the Magdeburg city one summer evening in 1934. I am sure of the because in the afternoon I had listened to the raucous voice explaining why he had slain his Roehm. The fractured limb was wrapped in saturated with the oil and then immobilised in a splint. Oily pus oozed from the case, a piquant contr to the carbolised asepsis of the other surgical war for Dr. Löhr was one of the first disciples in Germany Joseph Lister. Did the fractures heal in their unbo bath? Yes, without exception, without pain, witho fever. I brought the news home with me and heard similar success in other hands; one of them put t treatment on a scientific basis by inquiring into t vitamin content of the oil. Then came the sulphonami epoch and the oil was outdated and forgotten. I too h forgotten until last week when Timothy, my white to returned from the vet where he had gone for a septic b (my sister also has a tom). "Dress the wound freely on a day with this lotion," said the vet. "I'm afraid doesn't smell very nice. We emulsify the sulphonami with cod-liver oil. We find it works better." Thus d my accursed smell come home to roost.

* * *

I understand that, when an ancient monument h to be dismantled, a true and faithful record is made all that it contains. As an obituarist of long—if not hi —standing, I feel sure that there is an example to followed here, and, thinking as usual of our old frie posterity, I should like to plead for more bilaterali in obituary writing. The present tendency in obituari graphy is to dwell at tedious length on the thumpi virtues of the lamented. One or two of his more endeari foibles may receive passing reference, but little or no spa is devoted to his vices, follies, flaws, or weaknesses character. Reading the obituaries written now th historian of the future must assume either that we we all plaster saints or else that our obituaries have n historical value. This, I think, is a pity. One realise of course, that such bald statements as "except for monotonous habit of beating his wife every Saturday night, X was a monument of civic virtue" may come an unpleasant reminder to his widow; on the othe hand, to feel that she will no longer have to endure tho all too frequent castigations has its cheering side.

One further point. Obituaries ought to be writte ante-mortem and we should all be given the opportunit of reading, but not altering, our own. This might stimu late us to strive for good ones and result in a remarkab moral improvement all round. What could be pleasante than to receive one morning a revised and more laudator draft?

* * *

At this morning's surgery a lady mentioned that on of my colleagues had given her husband penicilli lozenges for tonsillitis. My suppositories had not cur her bleeding piles, she continued, and so she had used couple of the penicillin tablets with immediate a lasting relief. Her elation at this therapeutic triump filled me with a wild surmise concerning the stypti and healing properties of local penicillin. I racked my brains in vain for details of its rectal use, marvelling a this gap in the vast literature on the antibiotic. Proceed- ing cautiously I first inquired if she had actually inserted the tablets per anum, but unfortunately for my projected paper it turned out that she had swallowed them.

* * *

When we first had him as a very small kitten we weren't sure of his sex so called him Doubtful Thom When, in the light of his subsequent behaviour, Since doubt was removed he became True Thomas. His recent operation he has lived up to that name. attack of what the vet calls "cat flu" has been a matter of the gravest concern. The drawing-room has been turned into a private ward and other work has had to receive that continuity of management which is essential to the successful outcome of ent.

ria Hospital, Blackpool. **DAVID L. CALDWELL**
Assistant Chest Physician.

—The correspondence evoked by Mr. Francis's of Sept. 24 indicates the concern felt regarding the t position in the "control" of tuberculosis. Yet are those who are conscious of the advances that een made and who believe that tuberculosis may trolled by "combined operations."

close coöperation between an alert general-practi- service, an efficient hospital service, and the health ment of the local authority, it should be possible t the condition effectively. The so-called division inistrative control does not, I submit, present the les that some see in it. The transfer of the facilities agnosis and treatment to the regional hospital establishes a closer link with the hospital, and es greater freedom of action for the chest physician, no longer bound by considerations of local and mental finance. The retention of the preventive vironmental services by the local health authority s on that authority the responsibility for social ine. Thus the two sides of the disease—individual ocial—are linked through the physician to the clinic, whose function is to view each patient as cal point for the "combined operation" of domi- and hospital treatment, and thus to marshal not the hospital services for the treatment of the dual, but also the several departments, both l and voluntary, that alleviate the economic n of the household and prevent the spread of ion.

he sphere of treatment there still exists the antag- between the devotee of conservative methods and eliever in a more active approach. While bed rest ays the foundation of treatment, it often does not by itself, and it is wise to use a combination of arious methods, both in the home and in the al, being ready to change the combination as the t's condition fluctuates. The ideal place for such a en is the hospital or sanatorium, but unfortunately t-term" admission to hospital for the induction lapse commonly results in prolonged hospitalisation o complications; and the "quick turnover in the orium"—to quote Dr. Hoffstaedt (Oct. 8)—just not exist. Domiciliary induction is fraught with too dangers to be undertaken lightly, though it may value in carefully selected cases. The complications llapse therapy are so common and of such sudden ften inexplicable onset that a casual approach is to voided. The patient should not be encouraged to on collapse therapy or any other *single* method of ment as a sheet-anchor, but should be trained to the position steadily and to see it whole.

the other hand, administration of chemothera- c agents in the home, if governed by regular patho- l assessment, may prepare a patient, without risk, urther and more active treatment on admission to ital; or conversely it may arrest decline in a condition is not responding to collapse therapy induced at an er stage. I sympathise with Dr. Temple Clive in desire to "receive patients 'pre-conditioned' by rest only," but I believe this ideal cannot be attained e the shortage of institutional beds continues. It nperative that some form of treatment should be d to bed rest and ancillary nourishment in order bviate the decline that often takes place under ciliary treatment. At the time when the patient is itted to a sanatorium, a detailed report of all findings, skiagrams, should be supplied by the chest physician ct to the sanatorium physician.

For the control of tuberculosis we require:

(1) Early reference of suspected cases to the chest clinic by the general practitioner.

(2) Efficient means of diagnosis at the chest clinic.

(3) "Pre-hospital conditioning" by a planned combination of selected methods of treatment.

(4) Prevention of the spread of the disease by public health measures, by regular examination of "contacts," and by regular mass-radiographic surveys of selected groups of the population.

(5) Hospital inpatient treatment of the patient.

(6) Subsequent vaccination of tuberculin-negative contacts with B.C.G.

(7) A gradual and graded return to work in the more successful cases, with regular inspection of patient and "contacts" at frequent intervals.

(8) Adequate housing of the population.

Until these can be attained those working for the alleviation of tuberculosis must coöperate in a systematic combined operation.

D. L. PUGH
Chest Physician, Mid-Kent Area,
South-East Metropolitan Regional Hospital Board.
Maidstone.

CATALOGUE OF MEDICAL FILMS

SIR,—Two years ago, with the aid of a generous grant from the Royal Society of Medicine, the medical committee of the Scientific Film Association set up a master file of data on medical films. This includes details of production, distribution, and content, and a provisional grading of each film. It covers all the films in existence in this country up to 1946, and is being added to constantly. With details of over 800 films, it provides the most comprehensive collection of data about its medical films that any country in the world (with the possible exception of Canada) can show. From this master file was prepared the R.S.M.–S.F.A. catalogue of medical films. The first edition of 1000 copies was exhausted in twelve months—a remarkable index of the widespread interest in medical films.

We were faced with the problem of deciding whether to reprint or to prepare a new edition. As the lay-out of the first edition was cramped by paper shortage, and as there are many new films to be included, we have decided in favour of a new edition. We are constantly getting requests from abroad as well as from this country, and we ask the hospitality of your columns for this explanation of why the catalogue will not be available for some months yet.

Scientific Film Association,
4, Great Russell Street,
London, W.C.1.

KENNETH GOADBY
Chairman, Medical Committee.

URÆMIC ŒDEMA OF THE LUNGS

SIR,—Since the publication in 1947 of an article on "uræmic" œdema of the lungs,[1] I have had a number of inquiries concerning radiographs showing typical shadows in the lungs of patients who were not uræmic. The following note is an attempt to clarify the position.

During the past fifteen years there have been occasional descriptions of radiological changes in the lungs of patients with hypertension and renal failure variously designated as "uræmic" or "azotæmic" œdema or pneumonia. The pathological findings in 4 such patients who died formed the basis of my own investigations: in these the lesion causing the shadows proved to be a non-infective albuminous and fibrinous pulmonary œdema in varying stages of organisation. In a further, non-fatal, case the shadows rapidly resolved with rest in bed, and it was postulated that their basis had been a purely albuminous œdema. The pathological changes are identical with those in so-called rheumatic pneumonia: indeed fibrinous œdema from any cause may give rise to the same microscopic picture. I believe that,

taught, does not carry conviction. Hitherto there has been no suggestion that the doctors produced by St. Mary's are less capable than their colleagues.

My committee feels a need to work hard to bring about the final decision in the near future, since a hospital which is under threat of annihilation works under strain and it is only a matter of time before signs of deterioration must appear through the unwillingness of serious workers, whether doctors, nurses, or others, to spend their energy on tasks which have no relation to a future.

Surely the proper course is to allow the Children's Hospital to continue the work which it has carried on with acknowledged success for sixty-six years, and to allow its teaching facilities to be transferred to another teaching-hospital group less fortunately situated than St. Mary's.

MICHAEL HARMER
Chairman, Save the Children's Hospital Committee.

ACUTE LARYNGOTRACHEOBRONCHITIS TREATED WITH CHLOROMYCETIN

SIR,—In their preliminary communication of Oct. 22,[1] Professor Moncrieff and Dr. Weller imply that hitherto acute laryngo-tracheo-bronchitis has been uninfluenced by chemotherapy. In my own experience chemotherapy and treatment by antibiotic have reduced the mortality. I am allowing for the wide variations in the severity of acute laryngo-tracheo-bronchitis—it is not uniformly an "alarming emergency"—and also for the present enfeebled virulence of streptococci and staphylococci.

On the subject of ætiology the writers state: "There is some evidence that it is caused by a virus." A few lines further on they refer to it as "the infection" but do not refer to an invasion of the tracheobronchial tree by pyogenic micro-organisms—the final cause of acute laryngo-tracheo-bronchitis. There is a good deal of evidence that the process ending in acute laryngo-tracheo-bronchitis is initiated by a virus such as that of influenza or measles or variola or the "common cold"; the "softened" mucous membrane is then secondarily invaded by the hæmolytic streptococcus, *Staphylococcus aureus*, the *Hæmophilus influenzæ* type B, or the pneumococcus. There is some evidence also that the complete symptom-complex can be caused by the pneumococcus or *Hæmophilus influenzæ* acting singly.

These micro-organisms have been recovered in acute laryngo-tracheo-bronchitis from the oronasopharynx, the larynx, the trachea, and occasionally the blood-stream. The picture post mortem is typical of an overwhelming infection by pyogenic micro-organisms. The symptom-complex is also of course seen in adults. It is not unreasonable to suspect in the case of Professor Moncrieff's patient, who showed dramatic improvement, that 'Chloromycetin' may have directly affected the pyogenic micro-organisms. The scope of action of chloromycetin is wide.

As an adjuvant measure bronchoscopy is usually harmless; but when the child becomes "dry," when there is a gummy, crusting exudate in the tracheobronchial tree and necrosis of the mucous membrane, bronchoscopy is harmful and distressing. At this stage, too, oxygen just adds to the dryness. Indeed when the child becomes "dry," steam from a kettle or other humidifier is the only treatment of value, though at the moment it appears to be out of fashion.

In the penultimate paragraph of the article the writers say: "It will be noted that the children who survived were those in whom tracheotomy was performed early." If tracheotomy is done early it will in many cases be done unnecessarily; the child must be given a sporting chance to get through on his own—delay will
tracheotomies and avoid some deaths.

It is only too true that in the acute case all
may be useless, and it is difficult to see what tr
can prevent the acute myocardial failure or supra
œdema which may be precipitated in a few hour
fact death appears to be inevitable if the inf
really acute. In the less acute case recovery s
takes place unexpectedly. Such an unexpected re
occurred in Professor Moncrieff's case, and we
hope that it was due to chloromycetin—for we
need an effective remedy for acute laryngo
bronchitis.

Grove Hospital, London, S.W.17. J. C. McE

CHARGES FOR PRESCRIPTIONS

SIR,—The announcement has been made quite
that it is the intention of the Government to
a charge upon all prescriptions. There is general
ment that in the case of a great many prescription
is very desirable indeed and will have the eff
reducing irresponsible demands for placebos and
domestic remedies. It is, however, needless to
out that there is a large class of patients who are
the periodical necessity of filling in prescriptions.
applies particularly to diabetics requiring insulin a
sufferers from pernicious anæmia requiring one for
another of liver or stomach extract; it further a
to those with many other deficiency conditions, of
myxœdema and diabetes insipidus are obvious exam
It would be a great hardship upon these patien
they were called upon to pay a charge every time
required the filling in of a new prescription.

It is to be hoped that in drafting the new regul
due attention will be paid to the requirements of
patients.

Director of the Diabetic Cli

CONTROL OF TUBERCULOSIS

SIR,—I have read with interest the letters of
Temple Clive (Oct. 22) and Dr. Jeanes (Oct. 29).
seems to me that they bring out the necessity for
chest physician to have complete control of the pat
from diagnosis, through the period of institutional tr
ment, and back to general management and follow
in the chest clinic. I realise that the organisation
such that in many areas this is not possible, but I th
that it is an ideal which should be kept in mind du
this period when so much reorganisation is going
Also where major surgery is required some breaks in
continuity are sometimes necessary.

Tuberculous patients are notorious for their att
ment to one physician, and I believe that their mana
ment is made much easier if the one physician and
immediate local colleagues, with whom he is in c
contact, are responsible for the complete management
the case.

If such a procedure as I have suggested is adopt
then the chest physician himself will have to deal wi
any complications that he has produced by his domicilia
treatment before admission, and will not be able to p
on the clinical problems that he has created to a d
colleague. This will make him more careful in
selection of cases for collapse therapy and will teach h
by experience—bitter, if necessary—the right type
case in which to try active domiciliary treatment, a
the effects of para-aminosalicylic acid on the cour
the disease.

Close liaison between the chest physician respon-
for domiciliary management and the sanatorium phy
cian responsible for institutional treatment is essent
as Dr. Jeanes points out; but if the two responsibilit
could be amalgamated in one person, then the pati

fever may temporarily lower the level of serum osphatase where this has been high.

ins and Hodges [5] have shown that injections of rone propionate cause a rise in the level of acid atase in cases with bone metastases from carci- of the prostate. This "testosterone-stimulation , they say, most helpful in the differentiation tatic carcinoma with secondary growths from hyperplasia. They suggest that 25 mg. of testos- propionate should be injected intramuscularly r 15 days, and they recommend that the serum osphatase be estimated at least every other day.

J. G. ALEXANDER

n the article by Mr. Burgess and Dr. Winston the heading of table II (p. 791) should read: -acid-phosphatase levels in prostatic hyperplasia ned histologically."—ED. L.

PERATIONS FOR MITRAL STENOSIS

–Not everybody will agree with the surprise ed in your leading article of Oct. 29 that no t has been made to relieve the pulmonary nsion of mitral stenosis by creating artificial etence of the pulmonary valve.

ring possible active venomotor mechanisms (which, tive, would provide additional factors in support arguments set out below), the high pulmonary pressure and left auricular pressure can be due to all of three factors: the resistance of the mitral o the flow of blood through it; increased output right ventricle (this can only be a temporary ; or the regurgitation of blood from the left le. If, as Harken and his team are quoted as ; an operation should only be performed when s and regurgitation coexist, the last of these must important factor, and the high left auricular e therefore also represents a potential if not direction of flow "working back" through the nary circulation.

rtunately, Bland and Sweet [6] do not give details fluctuation- in left auricular pressure in their ts, but if the figures of 400–500 mm. (not ml!) er at all approximate to a mean pressure, creating ificial pulmonary incompetence might have unfor- consequences. Bland and Sweet's operation dis- of at least some of any regurgitated blood by ping" it in the systemic veins, which apparently modate it without any significant rise in pressure. he volume of blood, and consequently the pressure, (smaller) pulmonary venous system is decreased.

ne high pulmonary arterial pressure is necessary to ain the flow of blood through the pulmonary tion against the increased "peripheral resistance" ced by conditions in the left auricle (whether ely or actively), it is surely more rational to se this peripheral resistance (as is achieved by and Sweet's operation) than to decrease the of the right ventricle to maintain such a pressure.

possibilities can also be examined in a different It appears from Bland and Sweet's results that the volume of blood which "rushed with great force" gh the channel from the pulmonary into the azygos is insufficient to produce right ventricular failure h-output "self induced" failure. It would therefore re an extremely nice judgment in making the cial incompetence so that a chamber with such nctional reserve as the right ventricle would be nted from "flooding" the lung, without also ng right-sided congestive failure—a result which Bland and Sweet's operation (with the possible exception of case 5) appears to have the merit of avoiding. It seems reasonable to regard the operation as a semi-permanent, self-regulating pulmonary venesection—a form of safety-valve protecting the pulmonary venous system (and therefore the lungs) from excessive rises of pressure due to temporary imbalance between right and left heart-output or from the pressure of mitral regurgitation.

In the preceding reasoning there has been strict avoidance of the use of some more recent concepts of cardiac failure; but one cannot forbear from suggesting that the whole situation is more readily comprehensible in the light of McMichael's views.[7] Whether or not this is so, we have here an example of conditions in which conceptual reasonings involving injudicious interchange of "pressures" and "volumes," when pursuing a problem in hæmodynamics, is potentially dangerous.

All this is, of course, so much "arm-chair stuff," and the problems must be worked out on data gained in practice. This involves accurate pressure and flow measurements at all points in the circulation, especially in the neighbourhood of the left auricle—technically very difficult in any circumstances, let alone, I imagine, those obtaining at operation on these patients. In the meantime, Bland and Sweet's operation seems to have considerable empirical justification, and, to me, a fairly rational basis.

Middlesex Hospital, London, W.1. MORAN CAMPBELL.

HOSPITAL COSTS

SIR,—The estimates for the year 1950–51 are now being prepared for submission to the Minister by regional boards and boards of governors of teaching hospitals. Last week's leading article is therefore timely. I feel, however, that the placing of the main responsibility for the increased hospital cost on medical staffs is rather unfair and that the answer to this problem is not quite as simple as you suggest.

It has always been a well-established principle in the past that the person with the privilege of spending money should also have the responsibility of finding it. This is the prerogative of every family unit. Before the appointed day this worked out reasonably well in the case of both the voluntary and local-authority hospitals. An eye had to be kept on subscriptions or on the rates to be levied on the community. Owing to the sudden release from the "beggar state" of the old voluntary system and from the parsimonious atmosphere of some local authorities, the medical men working in hospitals may be asking for more and more elaborate equipment and costly facilities. The lay board to whom they report, having likewise no responsibility of finding the money, very naturally tend to leave the pruning of expenditure to the Minister. The Minister, with his lack of local knowledge, is in the worst possible position to do this effectively, and, as you say, is liable to "cut away the fruit buds with the useless wood."

It was a fundamental psychological error on the Minister's part to assume, when he framed the Act, that his local agents, being human beings, could be expected to act with the maximum sense of responsibility in the expenditure of funds coming from a "remote" source.

A method will have to be devised to implement more effectively the old adage about "cutting the coat according to the cloth." There have been various methods suggested. Boards, like universities, might be given a grant to cover five years and their expenditure would be limited to this amount. Under this system, however, the Minister would cease to have responsibility for the day-to-day running of the hospitals—a constitutional point regarded as necessary. It has also been suggested that new boards, democratically elected,

iggins, C., Hodges, C. V. *Cancer Res.* 1941, 1, 293.
and, E. F., Sweet, R. H. *J. Amer. med. Ass.* 1949, 140, 1259.
7. McMichael, J. *Amer. J. Med.* 1949, 6, 651.

as suggested by Rendich et al.,[2] heart-failure, not uræmia, is the basic lesion. The distribution of the shadows is in fact identical with that seen in the rarely obtained radiographs of acute fulminating pulmonary œdema due to left-sided heart-failure.

The interest of these "uræmic" œdemas which occur occasionally in hypertensive renal failure lies in (1) the paucity of clinical symptoms and signs, and (2) the fibrinous nature of the œdema in fatal cases. I have suggested that the uræmia so modified the permeability of the lung capillaries that they allowed the passage of a protein-rich transudate into the alveoli in patients suffering from heart-failure of only moderate severity.

The non-uræmic cases brought to my notice during the past two years were suffering from either myocardial infarction or mitral stenosis, with or without aortic valvular disease; and all had fairly severe acute heart-failure without clinical signs of fulminating pulmonary œdema. The lung shadows were not always bilateral; they showed a typical hilar distribution flaring out butterfly-fashion towards the periphery. Further similar radiographs have also been seen in hypertensive renal disease and in non-uræmic cases of fulminating pulmonary œdema, some of which resolved in a few days.

It would appear that in the spectrum of pulmonary changes in acute heart-failure, varying from congestion to fulminating œdema, factors other than the intensity of the heart-failure may modify the pulmonary picture. Uræmia is one of these factors. Another possible one, noted recently in post-mortem material, is severe anæmia. An obvious third factor is superadded respiratory-tract infection. The peculiar butterfly-shaped distribution of the transudate in the lungs remains an enigma.

Pathology Department, Postgraduate Medical School of London. I. DONIACH.

A PSYCHIATRIST LOOKS AT TUBERCULOSIS

SIR,—In your annotation of Oct. 29, you say that "the statement that the prevalent mood among the tuberculous is that of anxiety and depression will come as a shock to many." Later you add that "much the same situation confronted troops going into battle." These are formidable misconceptions.

The conclusion that people become depressed when stricken with tuberculosis is scarcely profound. In fact such is the only normal reaction. Nor is it easy to see why it should cause a shock to anyone. Certainly it is well known to every doctor who has worked among such patients—unless he has lost all insight into what constitutes true cheerfulness as against its studiously and intermittently contrived counterfeit. To give the impression that he accepts at their face value all the appearances of cheerfulness assumed by his patients may be an important part of his medical care; but to be himself deceived by what is often no more than a gallant attempt to put up a brave front upon an abominable affliction would be so ingenuous and complacent as largely to vitiate his worth as a physician.

How different is the strain imposed upon troops going into battle. Experience promises them swift exchanges of fear and exhilaration followed by hunger, exhaustion, and sleep. Death or wounds, if they should come, must come swiftly. The contrast could scarcely be more complete.

From this same analogy of war there could, however, be drawn an authentic parallel with the plight of the tuberculous. The prisoners did indeed find their malady to be one of "unknown and uncertain prognosis." Moreover it produced a like effect. During many months and years of hopes deferred their bizarre fluctuations of mood, inconsequential fits of gaiety and quick-changing hates and attachments, bitter of the privileges of the free, and dragging sense of diminishing contact with home, developed in attitude and a behaviour which mirrored with a exactitude that to be found in a sanatorium ward

Bristol. IAN MCD. G. STEWA

SERUM ACID PHOSPHATASE IN PROSTA CARCINOMA

SIR,—In your issue of Oct. 29 Mr. Burgess and Winston Evans come to the conclusion that the mination of serum acid phosphatase is of little val most cases of prostatic carcinoma. However, Her found that the serum acid phosphatase was increas 29 out of 35 cases of prostatic carcinoma with metastases, and in 12 out of 47 where there w radiological evidence of metastases. Sullivan e recorded an increased serum acid phosphatase in 11 of 130 cases of metastatic prostatic carcinoma, a 11 out of 70 where there was no positive eviden metastases.

The level of the serum acid phosphatase depend only on the character of the tumour producing pro phosphatase but also on the extent of invasion of and lymph channels and probably also on endog androgen production. It has been shown that a natural pH of serum, and at body temperature prostatic phosphatase is rapidly destroyed. The thus a balance of continuous inflow and destructi prostatic phosphatase when the prostate unde malignant change and invades the capsule.

A notable advance was made by Herbert[3] whe demonstrated that prostatic acid phosphatase in s is destroyed by alcohol; but acid phosphatase in no serum (produced by extraprostatic tissues such as spleen, bone, and kidney) is alcohol-stable. The mod increase in serum acid phosphatase sometimes fou bone and liver conditions (e.g., Paget's disease hepatitis) is all alcohol-stable, whereas in metasta prostatic carcinoma with elevated serum acid phatase, treatment of the serum with alcohol lowe titre usually to normal. Occasionally even when the serum acid phosphatase is not elevated a signi amount of prostatic phosphatase in the serum may e a diagnosis of prostatic carcinoma to be made. A con fall of more than 1 unit after treatment of the seru alcohol is almost diagnostic.

In 6 cases of prostatic carcinoma with bone meta I have found the initial serum acid phosphatase t markedly elevated and diagnostic in 3. In the oth patients the initial serum acid phosphatase was 5·5, 7·0, and 4·5 units per 100 ml. However, alc inactivation in these cases showed the presence of 3·0, and 1·3 units per 100 ml., respectively, of pros phosphatase in the serum.

It seems, therefore, that in all suspected cas prostatic carcinoma in which the level of serum phosphatase is normal or slightly elevated, it is esse to proceed further and carry out alcohol inactivatio the serum.

Manchester Royal Infirmary. M. H. OELBAU

SIR,—I am most interested in the informative paper Mr. Burgess and Dr. Winston Evans in your issue Oct. 29. They have, however, omitted two impor references.

Huggins et al.[4] point out that the patient's bo temperature at the time of taking the blood is import ιic one, but one of ethical and intellectual values, so to be judged by us. I hold with profound tion that a humane and learned profession must sole guardian and judge of its values, and cannot trade these away because times will be hard, or em in commission for monetary reward.

ugh I find some of my colleagues moved to an easy ynthetic scorn when they are reminded of the t remains true that we are the inheritors of the ratic tradition with all that this imposes upon l we may not hand over our values for grading by ern government, knowing as we do what are the erations that must move the modern politician: l-to-mouth expediency, a lust for power over the f their fellow-men, and half-baked ideologies that ıo roots in culture, no love of learning, and no of historical sense.

llow government to be our principal paymaster is ing, but it is quite another to permit it to impose us a crude, arithmetical classification of all those derables that make up true distinction in our sion. To do this is to abandon our responsibilities, me arrant materialists, and to condone the setting a false set of values that no-one can hold in t.

threatened evil is not less because learned bodies ıominated the members of the Awards Committee, so doing have given away what it is their prime o preserve. If they really understood what they loing, we should be forced to look upon their action regard as but another example of that "trahison ercs" that is at once a factor in, and a grim sign of, eneral lapsing of all standards that characterises me.

lon, W.1. F. M. R. WALSHE.

—Regarding this very great experiment controlled man nature, permit me to put forward the suggeshat all persons enjoying consultant rank be asked rticipate, in order that a true assessment may be ed. This could be done by private ballot, each ltant giving his opinion of colleagues of equal rank hospital and area and of his specialty in the ı.

Department of Pathology,
eral Hospital, Northampton. R. M. HEGGIE.

AMINO-ACIDURIA

—Your review of Professor Snapper's *Medical s on Bone Diseases* (Oct. 29, p. 798), referring to ni's syndrome, states that "There is no other n condition in which persistent amino-aciduria s." This is not true. Uzman and Denny-Brown[1] shown that in hepatolenticular degeneration on's disease) there is severe and persistent aminoria.

ave at present under my care a patient suffering this peculiar disease who excretes in his urine in 24 hours more than 1000 mg. of amino-nitrogen on rmal ward diet (normal excretion 100–200 mg.). In the case described by Uzman and Dennyn the total daily urinary excretion of aminogen varied between 800 mg. and 1500 mg. In neither ese two cases is there any clinical or laboratory ence of renal disease or hepatic cirrhosis.

e question that naturally arises is whether Wilson's se is the result of a fundamental defect in the bolism of amino-acids. The disclosure of the same abolic disturbance in unaffected members of the ent's family certainly suggests such an explanation.

rdıff. JOHN D. SPILLANE.

[1] zman, L., Denny-Brown, D. *Amer. J. med. Sci.* 1948, 215, 599.

VASCULAR STASIS

SIR,—I think that Dr. Sevitt has Dupuytren wrong in his letter last week. If the following translation[1] is correct, then the burns in which I have observed benefit from exhibiting anti-histamine drugs include Dupuytren's 3rd-degree burns:

> "(3) The cuticle is destroyed and also the superficial part of the true skin, but the interpapillary processes with their sensitive nerve endings are thus left exposed; hence burns of this degree are very painful and accompanied by great collapse. They are indeed the most fatal variety from this cause, and a very grave prognosis should be given if they are extensive, burns involving the neck, trunk or both limbs being usually fatal, more especially if occurring in young children. The sweat and sebaceous glands are not destroyed and healing will thus be rapid, epithelialisation occurring from all over the burnt area and normal skin being quickly reformed, no contractures or deformity resulting."

The last is an ideal often not reached in the past, partly because burnt tissue continues to liberate toxic substances for days which causes the death of structures which would otherwise have survived. This phenomenon has even been demonstrated in the partly burnt stems of woody plants (Strasburger's Textbook of Botany).

Manchester. S. SHUBSACHS.

THE DOCTOR'S CREED

SIR,—Professor Platt (Nov. 5) asserts that we must either believe that God "is powerless to intervene against the evils of Satan and of man or that they are of His own creation." Is there not at least a third possibility, that God, having given man free will, for the time being deliberately refrains from forcing His will upon mankind? If man were a robot he would have to do the will of his maker without question; but there could be no development of character, no choice between good and evil. Neither is there any reason to assume that an omnipotent and omniscient God would necessarily be good.

There were doctors at Buchenwald and Auschwitz. How could Professor Platt prove that the behaviour of such men was criminal or that their implicit obedience to Hitler, Himmler, and other demigods was wrong? If it is denied that each man has an immortal soul, how is it possible to argue that all men are entitled to equal rights? A strong case could surely be made for concentration camps and the totalitarian régime.

Professor Platt talks about conscience, but this word connotes a conception of right and wrong. What is right and what is wrong, and what is truth? Were the doctors at Buchenwald camp justified in doing what they did if they thought they were right in obeying Hitler? Is private judgment the criterion; or are there eternal verities, and if so how are they to be discovered?

The evolutionary theory is concerned with the development and survival of the species and offers no evidence to show that truth, goodness, and beauty have operated any more than ugliness, bestiality, and vice in the survival of man. Indeed, it may seem that bad faith, bestiality, and cruelty may in the near future prove more potent and successful than goodness.

There are, it is true, many earnest doctors and beloved physicians who do not subscribe to any orthodox religious belief; but I venture to submit that they are all living on borrowed spiritual capital and are heirs of a Christian environment. There is no evidence to suggest that Christian ethics could survive for long apart from the witness and influence of men and women who truly accept and practise the Christian faith.

It is because every member of the medical profession holds Professor Platt in such high esteem that I venture should be set up with the power and responsibility of finding at least a proportion of the expenditure by levying rates. Doctors, however, have always been opposed to any kind of local authority administering professional services.

---

[1] Romanis, W. H. C., Mitchiner, P. H. The Science and Practice of Surgery, London, 1937; vol. I, p. 58.

Even an item of expenditure which is necessary for the best welfare of the patient cannot always be justified if money is limited and when there are perhaps stronger claims on limited resources. Someone said recently: "In a planned economy medicine may have to be rationed like any other commodity."

Cardiff. DAVID G. MORGAN.

BEDSIDE LOCKERS

SIR,—In your leading article of Oct. 22 you note the difficulty of finding a place for the urine bottle, and the undesirability of using the recesses of the locker for this purpose. A simple way of overcoming this difficulty is to provide a strong wire basket of the appropriate shape which hooks on to the underside of the bed. Two hooks go over the long bar of the bed frame and a small hook fastens the bottom or inner end of the basket to the underside of the wire mattress. This device enables the patient to reach for the bottle with the minimum of movement. It is cheap and easily made, and if the æsthetic aspect is important it can easily be covered with a washable jacket. This arrangement will be found much more convenient than using the lower compartment of a locker, or, as I have found in one London hospital, a waste-paper basket under the bed.

London. W. P. KENNEDY.

CASUALTY WAITING TIMES

SIR,—I have been reading your interesting annotation of Sept. 3 on the valuable inquiry made by Mr. Patrick Clarkson[1] into the time spent by patients in the "front surgery" at Guy's Hospital. There are two points on which I would like to comment briefly.

One is that the distinction which has been drawn between time spent and time spent *waiting* in a casualty or outpatient department is an important one. It is the long waits with nothing happening that are so tedious and irksome to the patient; time employed in procedures in which he is a participant may not always be pleasant, but it is less wearisome and is likely to be recognised to be necessary and unlikely to give rise to complaint.

The other matter on which I desire to comment is the welcome reference, at the end of your annotation, to the patients' comfort. It is not so rare as it ought to be to find patients waiting (e.g., for an X-ray examination) under conditions which would be trying to a vigorous healthy person and which are much more trying, and may even be injurious, to a sick person; this applies to inpatients who are taken from their wards for investigation and treatment in other departments, as well as to outpatients. Usually in such cases there is some fault in the premises, but matters could often be improved if more thought were given to each patient's comfort. All the members of the staff are busy with their duties and they may forget how hard a bench becomes after a time, or how irksome it may be to continue long in one position (e.g., lying on one's back on a patient-trolley), or how much a sick person may be suffering from a draught which they, actively engaged, do not notice. Draughts are probably the source of the most acute discomfort, and unfortunately they are very common. The possibility of giving some protection by screens should not be overlooked. Sometimes one even encounters failure to take such an obvious precaution as seeing that a patient sent from the ward is sufficiently and suitably wrapped and (if necessary) a hot-water bottle. It might help matters if were definitely charged with the duty of arrangements for the comfort of waiting patients.

As a rule, however, the root cause of the in the premises; and this, again, is often many of the faults of our hospitals today—to the that most of the hospitals were designed for a different set of conditions from those prevailing Thus, patients may have to wait in a corridor be the need for special provision for them had not when the hospital was designed. The tremen growth in the volume of work imposed on co departments of hospitals (notably X-ray departm within the last 20–30 years, has given rise to m difficulties, because expansion of departments has been able to keep pace with the calls upon them. In ciency and unsuitability of waiting places are among many defects now crying out for remedy and aw the day when the only satisfactory remedy, involves new building, can be applied.

Ministry of Health, London. T. S. McInto

THE DISTINCTION AWARDS

SIR,—The importance of the issue must be my e for craving the further hospitality of your columns the question of "distinction" awards.

We must agree with Dr. Russell Brain (Nov. 5) the consultant body bears the major responsibility the situation in which it now finds itself. Ever since nationalisation of medicine became a live issue, it retreated step by step before the growing menace of central control of medicine, until at last it has bee possible for the registrar of the Royal College of Ph cians[1] to boast that the college is "unanimously" favour of coöperation with the Awards Committee.

Bowing to the so-called inevitable has become addiction with us, but we can scarcely plead in def that all this has happened simply because "we neg to inform ourselves" of what was in process. On complete political naïvety could have blinded us to destination of the path upon which we have chos enter—namely, the path of least resistance. The hop confusion of thought that characterises us is seen those who continue to drift along this path can be c "constructive" by Dr. Boldero in the letter I h referred to, and those who will not condone this are called "supine" by Dr. Russell Brain. Have w ceased to have their proper meanings for us?

If what is at stake were purely an economic issue, t would be some force in Dr. Russell Brain's defence distinction awards. Yet, even so, I find it hard to un stand upon what grounds of equity or logic he can s the egalitarian down-levelling of the N.H.S. as f the general practitioner is concerned, and yet fi objectionable for the consultant.

Are we not all members of the same profession, are not gifts of character, intellect, and profes ability as freely—if as unequally—distributed amo those in general practice as amongst consultants? I assumed that the consultant is a select and supe person for whom preferential terms may be asked? surely, upon any true assessment, the select man is he who asks more *for* himself, but he who asks more himself. And is this rare virtue a prerogative of consultant?

Little as, I am sure, Dr. Russell Brain would w so, he is in effect bidding us, with Omar Khayy "take the Cash, and let the Credit go, Nor hee rumble of a distant Drum!" For the truth is—and tainly my thesis is—that the issue is not primari mire so much its sincerity that I want to show he contradiction between the omnipotence and lence of God may be more apparent than real.

od's existence is accepted, and with it His omnipo- nd benevolence, there can be no *real* contradiction attributes, for the following reason. If He is not lent He lacks something. If He lacks something nnot be all-powerful in the strictly metaphysical

ever, there is an obvious need for reconciliation n a God who is accepted as benevolent and a twisted in agony. Dr. Platt's particular example rve us well. On the one hand is a God, good and ; on the other is Buchenwald, a pit of insensate . The churchman, he predicts, will use the following ents to cope with the difficulty: (1) that these atters of Faith which we do not understand: t Buchenwald had some divine purpose incompre- le to man. They both resolve to much the same and I believe no intelligent Christian would use argument and feel he had solved the problem to isfaction. Incomprehensibility can solve absolutely g.

t there is a great difficulty and a heart-aching m here is as freely admitted by the theist as the . Nor has the theist the monopoly of things hard lerstand.

I suggest two or three arguments in connexion this problem which may serve to express the ian view. Firstly, what does benevolence mean? ans "wishing well." What good thing does God us? The theist replies, Himself. That is our sole se . . . not good health or prosperity or comfort. od. I believe that suffering does not interfere with urpose. I believe, from personal experience, that npossible to reach maturity without it. Secondly, theist suffering has a meaning . . . and a meaning nvolves our good. Thirdly, that meaning was made clear to us many years ago when God was mauled roken and died in blood and violence. He knew ng . . . and He knew His purpose . . . and the id not contradict the other.

aster. FRANK S. RICKARDS.

—It is most curious to an observer trying to be tial that Professor Platt should find in the existence rces of evil (typified, if he will, by Buchenwald Auschwitz) the chief objection to the creed of ianity. It is the existence of these forces of evil, urse, which Christianity claims as its only raison and they alone can make the enlightened nism, which Professor Platt advocates, a broken

there were no evil, Christianity would be totally essary and humanism enough to enable man to his destiny.

versity College,
ndon, W.C.1. R. H. HARDY.

—The reasons given by Professor Platt for his lief in God and Divine purpose in the affairs of this l have often been advanced. Man was originally ived in God's image, but the Fall of man changed is and in consequence the character of the world. ng as this situation lasts, so long will man be the m of the abnormalities and diseases which cause all distress.

take the argument a stage farther. Why does behave so badly that wars recur with sickening ency? Is not this because man has on the whole, for so long, renounced Divine direction and tried to age things on his own, exercising that free will h distinguishes him from the animal world?

ndon, W.1. W. R. THROWER.

SIR,—Professor Platt has done us all a service by pinning down his objections to a concrete instance (i.e., the child dying of leukæmia), but perhaps he has forgotten that Christianity cannot be explained without Christ. The anomaly whereby a God of love should allow a child to die of leukæmia is explained for the Christian by the equally astounding anomaly that He should allow Himself to suffer murderous death by crucifixion. The Christian postulates that the divine resolution of the anomaly of the child dying of leukæmia was achieved only after the divine identification with suffering man at the crucifixion, and goes on to say that human salvation is only possible by appropriation of the divine solution—in other words, by an emotional and intellectual adjustment to the death and resurrection of Christ as being the clue to all moral, theological, and ethical problems.

Liverpool. S. L. HENDERSON SMITH.

SIR,—Everyone will appreciate the sincerity of Professor Platt's letter and welcome the reason he gives for raising the problem of relating "the evils of Satan and of man" with an omniscient, omnipotent, and benevolent God. He feels that this difficult question should be answered "because it must be the stumbling-block of many thinking persons on the threshold of religion." He will not accept the answer that "these are matters . . . which we do not understand" (I have omitted two words—"of Faith"—which he has inserted I know not why). Surely there can be no other answer: for the problem of evil, carrying with it cruelty, neglect, and disease, seems beyond the range of human understanding, and so long as that is so we should openly admit it.

It can be argued that some suffering is helpful, and William Temple has written "A world in which both suffering and sympathy exist is preferable to one with neither"; but much of it is sheer waste and tragedy, evil and cruelty, serving, so far as we can see, no possible purpose. When we are asked the question "What is the origin and meaning of evil?" Christians and agnostics are equally unable to answer. Christians believe that God, the origin of good, has revealed himself to man by Christ, and we all know that the origin of evil has not been revealed. Without such revelations these origins, outside space and time, are probably beyond the reach of human discovery. A link is missing. Many able men have, like Professor Platt, regarded this as a bar to the acceptance of Christ as the revelation of a wholly loving God: others, equally appalled by evil and equally incapable of finding an answer, have yet accepted the revelation and learnt to love and follow Christ.

Many wise men believe that Christianity is the only remedy for this very sick world. Should the great remedy of Christian love and fellowship be disregarded because evil, the very thing it eradicates from the life of men, is unexplained?

All of us, Christians and agnostics alike, hate evil and cruelty. We Christians believe that we can ally ourselves with God in the fight between good and evil, God and Devil, a very real and critical fight here and now; and we hope to fit ourselves, by God's Grace, to continue that fight in the next world to the end. Without doubt, Professor Platt and his like are on the same side; it is sad that he should find himself unable to share with the Christian the joy of membership of God's family, and fellowship, come what may, with our Lord Jesus Christ. Yet it is likely that one day a great many agnostics will be found among the sheep on His right hand and Christians among the goats on His left.

Oxford. G. R. GIRDLESTONE.

to suggest that the observations in his letter should not be invested with the authority of his medical status.

Bradford. G. W. THEOBALD.

SIR,—The Christian doctrine states that God made man, *the highest of all living creatures*, in His image; and because of this He gave man some of His attributes, one of which is freedom of will. Man may practise virtue or vice as he chooses. He may select deliberately (not by instinct) and follow any line of action from among many. If man chooses to make a Buchenwald or an Auschwitz, God will not interfere. To do so would be to destroy free will, and man would no longer be the image of God.

However, God earnestly desires man to do only right and good. It is untrue to say that "because I have within me an instinctive knowledge of right and wrong, it must have been given me by God." There is no such instinctive knowledge. We must deliberately separate right from wrong from the moment we leave the womb until our last breath expires. To guide us, we have the Christian doctrine and ethic, the Testaments, and the Gospels. We have an example in the life of Jesus Christ, whom we believe to be God come to this earth. God desires that we shall follow this rule and example, and recognise the gifts He has given us in private prayer and public worship, and He will strengthen our resolve with the Sacraments. We may choose, however, as we wish and follow whatever path we desire whether good or evil. It is a decision we must constantly make and remake all the days of our life.

"The inner satisfaction of doing right" can only come to those who know what right is. The only yardstick we have is the Christian code. To follow the Christian code is to follow Christ. "Ye that are not with me are against me." There can be no halfway house and no standing aside. It is as simple and as difficult as that.

I do not know whether leukæmia and nephritis are examples of evil. No doubt there are some who would say that they are. It would be valuable to have enlightenment on this point.

Richmond, Surrey. J. C. HARLAND.

SIR,—The tone of Professor Platt's letter, breathing a great love for his fellow-men and a desire not to hurt the religious susceptibilities of others, suggests that he is far from being an atheist. None the less, by finding it impossible to believe that God is omniscient, omnipotent, and wholly benevolent, he is by this limitation of His perfections, denying His existence.

There is no point in the comparison he makes of students questioning his decisions and his own criticism of the Almighty. He and his students are finite beings, while between himself and his Creator there is the gap of infinity. A better example of the same order is provided by Lambert.

> "A boy stood near the railway gazing philosophically at a passing train. A burning cinder from the smoke-stack struck him in the eye. He mused on the incident in this way. 'For me it is hard to see what design or plan this great Corporation could have had in spending vast sums of money to throw that cinder in my eye. *It is somewhat difficult to discern design or benevolence in it.*'"

A doctor at his best can give little assistance to his patients if he only knows what they are made of. To help them fully—that is to enable them to achieve their destiny—he must know what they are made for.

A reasonable conclusion to arrive at is as follows. God *is* a fact. Suffering is a fact. We do not fully comprehend why God should have permitted suffering nor how He adjusts *compensations* which seem to be required if justice is to prevail. But that we do not fully comprehend these things does not surprise us there are thousands of lesser problems than this we have failed to solve. We are not going to what is certain and maintain that our finite intellig ought to be able to comprehend everytning—a com hension the possibility of which experience absol denies.

It would be well to remember that the symbol *Christianity is a cross!*

Wolverhampton. PATRICK E. CARROLL.

SIR,—I believe that we, as a profession, are at ris *that* our life-long scientific training may *fail* to fit us weighing evidence of a different sort—the historical are apt to regard it as less factual than the findings of own researches. It will be noted that Professor P not once in his letter refers to the personal figure Jesus Christ: most Christians would agree that "Ch tianity without Christ" can make no sense at all to impartial inquirer. But if the historical evidence weighed, and the New Testament be evaluated in *light, men of science may find it more* than "unsa *table* hypothesis." Instead of straining "to believe to us is incredible" they may find their reason accep the catastrophic historic event of Christianity, with follows from it. To us as a profession it may be of inte that Luke, a man of our own discipline, became intimate historian of the origins of Christianity. Mod historians have borne tribute to the precision of his w It was given to a doctor to trace the records of the sup natural in history, which Christians take as authe cating the supernatural in doctrine and belief.

Professor Platt finds an insuperable obstacle to Ch tian belief in the facts of our daily clinical experience children dying of leukæmia or nephritis. *This* obs might well balk us if physical death were the end of But the Christian expectation is far otherwise. objection stands or falls with the materialist philoso which underlies it, yet without yielding an alterna solution for the *problem of pain*. Christians respect ev the tragedy of life, giving thanks that "all our joy touched with pain . . . so that earth's bliss may be guide, and not our chain."

Then *Professor Platt* sees *no* alternative betw agnosticism and a preposterous belief in Divine co vance at the evil of Buchenwald and Auschwitz. this oversimplification ignores human responsibility the right use of free will. concerning *which* Christia makes positive affirmations. If, in face of the ph sophical problems involved, free will be *abandoned* fo stark determinism, then whence shall the agnostic doc derive his ethical foundations? What would be meaning of "a sense of personal responsibility," "rig "truth"? Despite the stoic dignity of the agno stand, his security in assuming it may be questio "We have probably almost exhausted the moral ca we have inherited from Christian ancestors wh theological beliefs we now feel free to *reject*."[1] *concept* of a man's conscience, unilluminated by a hig authority, may be challenged as too subjective for creed of a *doctor*.

A suggestion in Professor Platt's closing paragra would have been vigorously *repudiated* by St. Paul namely, that religious faith may be allowable for its val to those who seek comfort. "*If* in this life only we ha hope in Christ, we are of all men most miserable."

Doncaster. CEDRIC C. HARVEY.

SIR,—Dr. Platt's consistent and *clear-hearted* let stimulated by the Archbishop's essay, was a joy to m It is because I do not subscribe to Dr. Platt's philoso ed under a national service. This amounted to considerable sum.

subsidies were a delicate and difficult subject. ennell suggested that certain essential foodstuffs, , say, wheat, meat, and certain fats might continue subsidy at approximately the present rate; but e subsidy could be diminished for other foodstuffs. ould lead to a rise in prices and a reduction in ges.

ying to the debate for the Government, Lord HAM, Minister of Civil Aviation, said the Labour and other Parties had not devised and operated eat social services merely because they wanted r to win a reputation as Santa Claus. A tremendous idealism and hard work had gone to the creation e services.

Opposition amendment was carried by 116 votes

Nurses Bill

he House of Commons on Nov. 4 this Bill was ered on report. A new clause moved by Mr. nsop, parliamentary secretary to the Ministry of , to impose penalties on persons who falsely nted themselves as being included in the list of kept under section 18 of the 1943 Act, was read nd time and added to the Bill. The report stage ncluded and the Bill was read the third time.

QUESTION TIME

Morphine for Climbing Accidents

dron-Leader E. L. **Fleming** asked the Home Secretary s department refused the request of Mr. Wilson H. Hey, hester surgeon, that mountain rescue squads be allowed y ampoules of morphia for the speedy treatment of l climbers.—Mr. **Chuter Ede** replied: In consultation e Minister of Health I am considering whether it would sible to make arrangements, subject to suitable safe-s, for the administration of morphine to injured climbers. d not approve the arrangements which Mr. Hey has ed illegally since 1934 because they do not in my view e for adequate safeguards. Squadron-Leader **Fleming**: Wilson Hey submits to the Home Secretary another or carrying this drug would he consider it?—Mr. **Ede**: nly I will. I am anxious to meet the practical situation, annot wink at absolute defiance of the law for 15 years.

Doctors' Lists

J. F. F. **Platts-Mills** asked the Minister of Health if uld furnish a list showing the number of general practi-s with 2500, 3000, 3500, 4000, and over 4000 patients ered with them under the National Health scheme; and steps were being taken to reduce those cases where the limit of 4000 patients had been exceeded.—Mr. A. **Bevan** d: General statistics on this matter are not readily ble, but inquiries have been made of a number of An analysis of the information supplied by six different (not necessarily typical of the whole country) shows that ollowing numbers and percentages of doctors on the al lists of these areas fall into the different categories ed to by the hon. member. In compiling the statistics s engaged in partnership have been assumed each to sponsible for the average of the number of persons on partner's list, and doctors employing assistants have had lists notionally reduced by 2400 for each assistant.

e total number of doctors practising under the National th Service in the six areas concerned was 2429.

ize of list	*Number of doctors*	*Percentage of total number of doctors*
01 to 3000	323	13·3
01 to 3500	277	11·4
01 to 4000	234	9·6
er 4000	160	6·6

s there is some element of inflation in executive councils' ters, the figures in columns 2 and 3 may be higher than is ally the case. Executive councils were asked in November, , to request doctors with lists in excess of 4000 not to pt additional persons for inclusion in their lists (except tives of persons already on their lists living in the same se) until their lists had been brought within the permitted t. Executive councils generally acted on this request and e have gone further and used their discretion to require doctors to take further steps to see that their lists are brought within the limit.

Copies of Prescriptions

Mr. **William Wells** asked the Minister whether his regulations allowed British subjects who were temporarily leaving the United Kingdom to have copies of National Health Service prescriptions that they needed while overseas.—Mr. **Bevan** replied: There is nothing to prevent such persons from arranging with their doctors for copies of any prescriptions, but there is no obligation on the doctor.

Infant Mortality

Mr. **Thomas Reid** asked the Minister what was the rate of infant mortality for the latest available period and for a similar period before the war.—Mr. **Bevan** replied: The provisional figure for infant mortality in England and Wales for the third quarter of 1949 is 26 per 1000 related live births; the corresponding figure for 1938 was 42 per 1000 related live births.

Incidence of Homosexuality

Mr. J. C. **Maude** asked the Home Secretary how many male persons were prosecuted and how many convicted in the Metropolitan police area in the years 1938, 1948, and during the first nine months of 1949, of persistently importuning male persons for immoral purposes and for offences involving gross indecency; and how many of such persons received sentences of imprisonment or were fined.—Mr. **Ede** replied: In 1948, 476 persons were charged in the Metropolitan police district with importuning male persons for immoral purposes and 444 were found guilty. In the first nine months of 1949, 415 persons were charged and 392 were found guilty. In 1948, 486 persons were arrested for gross indecency between males and 211 were arrested in the first nine months of 1949. Of the 89 committed for trial in 1948, 82 were convicted, and of the 94 committed for trial in the first nine months of 1949, 77 were convicted. I regret that the other information asked for is not available.

Brigadier **Frank Medlicott**: Is the Home Secretary aware that there is a feeling that the amount of homosexuality in this country is on the increase, and that the state of the law needs to be looked into; but, more important still, is the Home Secretary considering the setting up of a committee to examine the social, medical, and moral aspects of this very grave problem?—Mr. **Ede**: It is a problem which has been present in my mind for some time, and I am considering whether it is necessary to make any formal inquiries into the possible growth of these practices.

Mr. **Maude**: Will the Minister tell me how it comes about that there are no figures available as to whether these persons were imprisoned or fined?—Mr. **Ede**: I will try to ascertain that information for the hon. and learned gentleman.

Supply of Artificial Limbs

Lord **Willoughby de Eresby** asked the Minister of Pensions what was the time now taken to supply artificial legs and artificial arms from the date of measurement and order: and the average time now taken for repairs to artificial limbs sent to the main repair centres of his department.—Mr. C. J. **Simmons** replied: The time now taken to supply limbs to patients requiring artificial legs for the first time is normally 13 weeks. The average time over all classes of patients including those requiring spare limbs is 36 weeks for legs and 30 weeks for arms. The average time taken to repair artificial limbs at the main repair centres is 8 weeks.

Replying to further questions Mr. **Simmons** said that the Ministry had given those who needed a limb to maintain their employment priority over other classes. But the making of an artificial limb was not a matter of mass production. The work was done by individual craftsmen and a number of fittings were involved so that the owner of the limb could walk without discomfort. A new factory had already started to produce artificial limbs. The demand was now declining and he thought that they had reached the peak.

As to the suction-socket limb, the Ministry wished to issue it generally only when they were satisfied that every possible improvement had been made. They had now 150 patients wearing the suction-socket limb on trial. Production of this type was much slower than of the ordinary limb, and the Ministry hesitated to impede the production of ordinary limbs too much until they were satisfied that the suction-socket limb would prove really satisfactory.

Parliament

Amending Bill in the Lords

IN the House of Lords on Nov. 1 Lord SHEPHERD moved the second reading of the National Health Service (Amendment) Bill, which has already passed through the House of Commons. After giving a survey of the provisions of the measure, he confessed that it was a somewhat disjointed Bill and not one which canvassed any wide principle or proposed any startling change. It was a minor Bill—a list of small things promised, of little difficulties to be remedied, and of frictions to be eased. It was the first of the National Health Service (Amendment) Bills, but it would not be the last. So far from apologising for introducing it so early Lord Shepherd thought it was a matter for congratulation that the Government, having found that some adjustment was required, had taken early steps to put it into effect. In the course of time as the service grew and became bedded down, the Government might have to call upon Parliament to make adjustments. In doing so, however, he believed that no attempt would be made to undermine the main principles on which the Acts were based.

Lord LLEWELLYN held that although the Bill was a minor one it did a major piece of work. He recalled that when three years ago the National Health Service Bill was discussed by their Lordships it was suggested that the partnership clauses would not work. "The difference between the House today and the last time," he continued, "is rather remarkable, in that last time the noble Lords, Lord Horder, Lord Moran, and Lord Webb-Johnson, were all here in full cry, if I may refer to those very eminent medical gentlemen in that way. Today, showing what a far better Bill this is, all three noble Lords are conspicuous by their absence." Therefore it was clear that the medical profession fully agreed with the measure. He would like the Government to inform the House whether the proposal to charge on prescriptions would be carried into effect in this Bill or in some other measure. He would also ask if the Government would extend the exemption which was to be accorded to old-age pensioners to the disabled ex-Serviceman who needed medical supplies for his actual disablement.

Lord CLYDESMUIR had heard that there was some anxiety among specialists in Scotland as to whether clause 12, which provided that regulations should not require specialists to be employed full time, was watertight. A case had been instanced to him of a Scottish hospital in which as a result of administrative action, by advertisement, the door was closed to anything but full-time employment of specialists. Lord SALTOUN asked whether clause 24 (enabling children under 16 in Scotland to be treated, on the initiative of parents or guardians, as voluntary patients in mental hospitals) would not interfere with a boy's rights according to the common law of Scotland. In Scotland, he pointed out, a boy of 14 is considered capable of carrying on his affairs.

The Earl of CORK AND ORRERY suggested it should be arranged for the patient to pay the proposed new tax on his first visit to the doctor. That would limit the number of people going to see the doctor in the first place and thereby cut down the mob in the waiting-rooms. It would also obviate the need for the doctor to go on prescribing coloured water and reduce the number of old women sitting talking and making a great noise when probably all they needed was a Beecham's pill.

Lord KERSHAW, replying to the debate, was unable to say whether the one-shilling charge would be brought into this Bill, but the matter was under consideration. The Government agreed that it should be dealt with promptly. The exemption of disabled ex-Servicemen would be considered sympathetically.

Food Hygiene

In the House of Commons on Oct. 31, on the motion for the adjournment, Mr. T. C. SKEFFINGTON-LODGE pointed out that 3270 outbreaks of food-poisoning were reported between 1938 and 1947. In 1938 there were 156; last year 904. Between 1937 and 1918 no than 246 deaths were recorded. Since the war had been a phenomenal growth in community and two hot summers had exposed many wea the food front. Was the Minister satisfied that, the housewife is not yet free to pick and choose, powers of inspection available under the Food Drugs Act were being applied rigorously enough himself believed that the law was adequate but enforcement often was not. The cause of "po was still a mystery—it might well turn out to be borne—all the more reason to look at the subj flies surrounding our food. The range of places in slovenly habits created danger extended from homes to luxury hotels. British standards of were bad and the model by-laws recently issued Ministry, although containing excellent tions, made no reference to smoking and the be safeguards fell short of what was really required

Dr. EDITH SUMMERSKILL, parliamentary secreta the Ministry of Food, said that the people of the cou did not seem to realise that it was for them to de new standards of hygiene and that the cure lay in own hands. She reminded the House, however, until 1938 food-poisoning had not been a noti disease; and only since then had the public-h laboratories supplying data on this subject incre from 12 to 50. Thus the country was today m conscious of food-poisoning. Finally, she urged ho wives not to tolerate standards of cleanliness in a cater establishment that they would not tolerate in th own households. They must have the moral courag make a protest and not go to the place again.

Social Services and Economic Policy

In the House of Lords on Nov. 2 and 3 a de took place on the Government's proposals to deal the economic situation. Viscount ADDISON, Lord P Seal, moved a resolution approving the lines of described in the Prime Minister's statement on Oct and Viscount SWINTON, for the Opposition peers, mo an amendment criticising the Government's plan inadequate.

Lord RENNELL said it was obvious that if there to be a substantial all-round economy on the th we were our own masters to economise in it, must c from social services and food subsidies. The recogn that some of these services had to contribute somet to our economies was shown by the imposition of a amount on prescriptions under the National H Service Acts. From the report on the operation of National Health Services which was made on Oc it appeared to Lord Rennell that there were a nu of other economies which could be made there, which would be both profitable and perhaps not burdensome. Last year 187 million prescriptions been dispensed which at a shilling each was approxima the £10 million referred to as an economy. Of co the economy might turn out to be greater because new charge might lead to fewer prescriptions issued. The number of spectacles supplied and pai last year was 5¼ million, and spectacles on numbered 3 million. It had been stated recently reply to a parliamentary question that the estim number of spectacles to be supplied in the coming was 9 million. Lord Rennell suggested that a contr tion of 10s. per pair of spectacles would not be out place. The same sort of contribution might be den from other sources. One figure contained in the rep was of great importance. Hospital-bed accommodati was given as 450,000 beds net. Assuming a 60% be occupation, 1s. a day for the occupation of a bed wo produce something of the order of £5 million, and would produce the best part of £10 million. It see to Lord Rennell that under the National Health sche savings or contributions of the order of £25 million wo not be impossible or burdensome, more especially if t reduced the admittedly unnecessary demands which being made in a great many cases. No reference was m to the number of outpatients' visits to hospitals, which the bad old days of voluntary hospitals provided a so of revenue which might have been slightly be

JOSEPH CORBETT MUIR

M.D. Camb.

E death took place on Oct. 29 of Dr. J. C. Muir.
for almost a quarter of a century was medical
intendent of Whipps Cross Hosptial.

seph Corbett Muir was born in 1872 and was
ated at the Leys School. Cambridge, and the
ersities of Cambridge and Manchester. He graduated
ambridge in 1897 and proceeded to the M.D. in 1901.
r holding various hospital appointments in
chester, he joined the staff of Plaistow Fever
pital. where he worked under Biernacki.

In 1908 he was appointed medical superintendent of Whipps Cross Hospital. where he remained until August. 1932. except for the years between 1915 and 1919. when he served with the R.A.M.C., and was for some time a prisoner-of-war in Germany.

Whipps Cross Hospital had only been open for some five years when Muir joined the staff, and its development into a busy. modern. and well-equipped general hospital is largely due to the advice which he tendered to the former West Ham board of guardians.

Muir was a man of strong personality. whose work was devoted to improving the conditions of the patients under his care. He was known as a strict disciplinarian. but nevertheless was very attentive in dealing with any problems concerning members of the hospital staff. many of whom appreciate the help that he gave them in difficulty. He was regarded by his colleagues as a practitioner of outstanding merit. and members of the consulting staff always paid considerable attention to his opinion on a difficult case. As a hospital administrator he was widely known throughout the country. and for a time he was president of the Medical Superintendents' Society. A keen sportsman, he played tennis for both Essex and Gloucestershire. and he had a very low golf handicap.

Ill health caused Dr. Muir to retire in 1932. and he had been living at Box. in Gloucestershire. He closely identified himself with the life of the district and was a member of the Stroud rural district council. His wife survives him.

RICHARD LAKE

F.R.C.S.

Mr. Richard Lake. consulting surgeon for diseases of the ear. nose, and throat to University College Hospital. died in Bristol on Nov. 3 at the age of 87.

The son of Thomas Lake. of Cheeke Court. Sittingbourne, Kent. he received his medical training at St. Thomas's Hospital. London. where he took the Conjoint qualification in 1885. The same year he took part in the Sudan campaign as a surgeon with the National Aid Society (the forerunner of the British Red Cross). For his services in the Serbo-Bulgarian war he was decorated by both sides, receiving the order of the Red Cross of Bulgaria and the fourth class of the Order of St. Sava of Serbia. After postgraduate study in Vienna he returned to England to specialise in otolaryngology and in 1887 he was appointed laryngologist to the Mount Vernon Hospital for Consumption. and soon afterwards to the staff of the Royal Ear Hospital, which later was associated with University College Hospital. He also joined the staff of the Seamen's Hospital, Greenwich. In 1890 he took his F.R.C.S.

From 1924 to 1928 he held the Geoffrey E. Duveen lectureship in otology in the University of London. and he also lectured at the Medical Graduates College and at the London School of Clinical Medicine. In 1907 he presided over the West London Medical Chirurgical Society. and in 1913 he was president of the otological section of the Royal Society of Medicine. For some years he was a coeditor of the *Journal of Laryngology* and his own writings included *Laryngeal Phthisis, Contributions to the Art and Science of Otology.* and (with E. A. Peters) a *Handbook of Diseases of the Ear* which reached five editions. He retired from University College Hospital in 1926.

Mr. Lake was especially interested in the re-education of the deaf. He considered that instrumental re-education is almost useless in acquired deafness of adults but most useful in congenital deafness and also of value in some cases of acquired deafness in children, to whom he gave devotion and skill. One of these congenitally deaf people "who showed signs of hearing after six months of untiring patience on his part" writes: "I see him clearly in his consulting-room in Harley Street, full of fun. generosity. and with an amazing fount of sympathy for those suffering from the handicap of deafness. He was full of inspiration and encouragement for he believed always that most deaf-born children had some residual hearing. All deaf-born and hard-of-hearing children are in Mr. Lake's debt for his pioneer work

Obituary

HERBERT LIGHTFOOT EASON

KT., C.B., C.M.G., M.D., M.S. LOND., F.R.C.S.

Sir Herbert Eason held office as medical superintendent of Guy's Hospital, as principal of the University of London, and as president of the General Medical Council. He filled each of these honourable positions after many years of devoted and loyal work for the institutions over which he was called to preside, and the following notes describe these three channels of service through which so much of his ability and energy were directed.

* * *

In 1920 Herbert Eason succeeded as superintendent of Guy's Hospital the late Sir Cooper Perry, who in 28 years of office had justly earned for himself an enviable reputation as a wise and able administrator. It was no easy task to follow such an one, but Eason had always had a tremendous admiration for the older man, both as an administrator and as a scholar, and he had taken advantage of every opportunity to study his methods. As the chief administrative officer of the hospital, the superintendent had nominal charge of all the individual departments, and Eason made it a point of honour to become thoroughly familiar with the routine and the personnel of every one of them. Throughout his period in office he paid a weekly visit to each ward and to each department, and there was no hospital activity, regular or irregular, of which his knowledge was not first-hand. It was said of him, with truth, that no-one could be more scathing in condemnation of careless or ill-done work and no one more generous in praise of work well done. During his tenure of office every official ceremony went off smoothly and without hitch, for he had always taken infinite pains to ensure the inevitable success and he had a real flair for this form of organisation.

[Walter Stoneman

He was a regular attender at the monthly meeting of the medical committee, and when, as sometimes happened, a discussion became discursive and threatened to become interminable, he would draft a resolution that covered the whole matter and satisfied everyone. A very clear thinker, he possessed such a quick brain that he was a great asset on any committee. As superintendent, he was accepted by both parties as the normal channel of communication between the court of governors and the visiting staff of the hospital, and he always regarded it as his most important duty to familiarise himself with the point of view of his medical colleagues and to represent it clearly and cogently to the court. His memoranda were models of their kind, lucidly expressed in perfect English, and it is not surprising if he was intolerant of badly worded and obscure compositions.

In his workaday office he was always readily accessible, alike to his colleagues on the staff and to subordinate officers of the hospital, and, even though he might not always be sympathetic to their case, everyone who approached him felt that he had had a fair hearing.

Eason was an accepted authority on the history of Guy's and he had an intimate knowledge of the place, its records, its traditions, and its atmosphere. To dine with him and his wife in the beautiful Georgian treasurers' house—destroyed in 1941—and to hear him expatiate on the portraits and pictures that adorned the walls of the governors' dining-room and the antique furniture which graced it created a lasting impression on the mind of many a young man in his house-officer days.

No man ever served a hospital more ably or more loyally, or loved it more. At the time of his retirement from office he himself said that he "valued " much as the goodwill of his fellow officers and and that he had enjoyed in abundance.

T.

I first entered the service of the University of in 1924. Eason was well established in the top of the hierarchy charged with the direction of university's affairs. He had already been chairman the academic council, but at the time of my had switched over to the chairmanship of the fi committee of the senate. Among my new masters, was the first of many to show me real friendliness— that friendliness developed into warm friendship. F the outset, he placed freely, but unobtrusively, at disposal of the raw novice the wisdom derived f experience and from an unusually alert intelligence. work together was interrupted he was invited to serve on departmental committee from recommendations the present stitution of the University of Lo derives. During this interim p he remained on the senate but on none of its committees senate membership lasted, in for 30 years.

Eason was a true Londoner his devotion to the university of his youth and his maturity probably one of the deepest loyal with which he was inspired. would be interesting to k whether he experienced gre satisfaction when, emerging f the tutelage of Cooper Perry, became superintendent of Guy's when, after a not too easy pa he became vice-chancellor of university. As vice-chancellor was at his best—and that best first-rate. Academically he was unduly adventurous, but he receptive of sound advice. public occasions he spoke well to the point. He never bored audience. Generally when he finished they would have liked more. No-one could quicker than he in solving practical problems—as example the planning and execution of the full we centenary festivities, attended by representatives universities and learned societies from all quarters the globe.

The last stage of his university career came at end of his term of office as vice-chancellor when in he was appointed principal in succession to Edwin De This change from the highest post, except for that chancellor, which the university has to offer, to that chief administrative officer was not an easy transiti But Eason, whose critical faculties were never allowed decay from disuse, and whose faults were rather f right than tortuous, effected it with success. And be principal of the University of London when evacu threatened disintegration of the whole machinery administration was no enviable task.

H. C

In 1925 Eason was elected the representative of University of London on the General Medical Cou over which Sir Donald MacAlister then presided. entered it, he relates, with considerable trepidati but it was not long before he found himself at home.

"There is in medicine," he wrote, "no society compar with an Inn, except the General Medical Council. The coun of the Royal Colleges of [illegible] are attra societies, but their const[illegible] re limited their particular branch of the profession. The General Medi Council, on the other hand, consists of the picked bra every branch of medicine, collected from every part of United Kingdom and Eire. They sit together all day du the session, lunch together, deliberate, and argue to in an atmosphere of cameraderie and good fellowship."

It was expected that when Sir Norman Walker reti from the presidency in 1939, he would be succeeded by oyal College of Physicians or the Glasgow Hunterian 1. Mr. Keynes notes that "all the portraits of are those of an old man, and there cannot be much e in the ages at which they were done." But after vey was 79 when he died; the two portraits Mr. accepts might well be of a man in his sixties, but f one getting on for eighty. There was time, after e painted, for him to be done again.

inating companion study would be the pursuit of s hands. Leaving aside the delicate ringed hand of ge of Physicians portrait—probably idealised or even gly invented by the painter—his hands are shown in gow portrait as strong, grooved, elderly (but not hands. How do these compare for age with the hands Ditchingham picture? Mr. Keynes, who has seen th, could tell us.

OST OF HOSPITAL ADMINISTRATION

tempting to ascribe any fresh increase in hospital the expense of a more lavish administrative machinery he N.H.S.; but the Minister of Health [1] has lately that the cost of administration accounts for only of total expenses; and he has declared that adminis- is "streamlined." In a report on the Bromley group, Mr. R. C. Millward, secretary of the manage- ommittee, gives the following figures for staff on l this year:

Department	*Total*		*% of total*	
ative ..		23		1·27
al	53		2 95	
ıg	654		36·23	
atory	24		1·34	
	13		0·72	
otherapy	38		2·11	
acy	9		0·49	
service	15		0·84	
		806		44·68
c	745		41·34	
	84		4·66	
		829		46·00
ance and transport		39		2·22
(serving all departments)		105		5·83
		1802		100·00

figures are exclusive of specialist medical staff. The figures estic workers include a number engaged part-time, while for nurses falls short by about 30 of the number desired for s at present open.

aff in other areas is in about the same proportions, it saving in the cost of administration can be expected nanagement-committee level: there may still be some nous administrators in our hospitals; but it seems e emergence into the management-committee's offices s and others who formerly worked unseen in the local ity's medical division gives a faulty impression of xuberance of numbers.

ESTIMATES OF FUTURE BIRTHS

he return of births and deaths for the week ended 9, the Registrar-General estimates that in England ales live births will number 171,000 in the quarter Dec. 31, 1949, and 186,000 in the quarter ending 31, 1950, making a total of 357,000 for the six months. six months ended March 31 this year live births totalled 4.

A MEETING ON MEDICAL LIBRARIES

of the results of the National Health Service Act has a great expansion in the provision of library services pitals. In this connexion hospital authorities are faced many problems and there is urgent need for help and nce, especially in the selection of medical books and licals. A memorandum by a special committee of edical section of the Library Association appeared in our ns on Sept. 3, and has now been published by the iation as a pamphlet, "Medical Libraries in Hospitals"; k-list has also been compiled. Requests for these have received from hospital authorities in Great Britain, a, Australia, Canada, Germany, Malaya, and the United s of America. Many correspondents have asked for er advice and for book-lists on specific subjects.

view of this demand and of the widespread interest which w being taken in hospital libraries, a special meeting he medical section of the association will be held at cer House, Malet Place, Bloomsbury, London, W.C.1, on Friday, Dec. 16, at 7 P.M., at which medical libraries in hospitals will be discussed. Members of the committee responsible for compiling pamphlet and book-list will endeavour to answer questions. Hospital authorities, doctors, and members of the Library Association are invited to attend.

A POET OF MENTAL ILLNESS

CLINICAL pictures are hard to paint in words, harder still in verse; yet Gustavo Augusto de Rezende, in a work [1] which has only lately reached us, has made the attempt, choosing the insanities as his theme. It is difficult to call the following English words poetry:

> "The arteries in sinuous curves
> Are hard and tense and of strong amplitude."

But almost the same words in Portuguese, and in almost the same order, fall rhythmically into lines which are both sonorous and metrical and achieve a sense of poetry without the embellishment of romantic metaphors and similes. The reason perhaps is that Portuguese verse is vastly different from English. Of these forty short poems, none of which exceeds fourteen lines, about thirty are clinical pictures of different forms of mental affliction, including schizophrenia, paraphrenia, erotomania, melancholia, mania, senile dementia, presenile dementia, general paralysis, heredosyphilis, cerebral syphilis, epilepsy, hysteria, neurasthenia, psychasthenia, chorea, epidemic encephalitis, constitutional psychopathy, idiocy, &c. One poem is called "Collective Psychosis (War)." The last poem in the book tells the reader (still in fourteen lines) how to avoid insanity. But it would take a Horace to turn out gems of poetry on these themes.

MEETING OF JOINT NUTRITION COMMITTEE

AN expert committee on nutrition, set up jointly by the Food and Agriculture Organisation and the World Health Organisation, held its first session in Geneva between Oct. 24 and 28, under the chairmanship of Lord Horder, adviser to the Ministry of Food. In some goitrous areas locally produced salt is not easily iodised; and the committee recommended that other methods of supplying prophylactic doses of iodine should be devised. Among the committee's further recommendations was one concerning the establishment of an international code of analytical methods for the determination of vitamins in foodstuffs.

BRITISH AND NEW ZEALAND MORTALITY

A RECENT study [2] shows that the expectation of life in New Zealand is considerably higher than in England and Wales. New Zealand mortality-rates are much more favourable than those for England and Wales in respect of most age-specific causes of death, with the greatest differences in the younger age-groups; "and from the figures . . . for infant mortality by social class it is clear that lower mortality rates can be achieved in England and Wales with better nursing, feeding, and infant care."

SCOTTISH DEFENCE UNION

THE annual report of the Medical and Dental Defence Union of Scotland shows that in the year ended Aug. 8, the membership increased by 204 to a total of 6300. The union's financial position is strong, with a reserve of £6 6s. 8d. per member. The past year, says the report, has brought no signs of any decrease in the number of claims made by patients alleging negligence in diagnosis or treatment; and the number of such claims against dental members has increased substantially.

The report offers advice to doctors who are asked by solicitors and others acting for third parties to give information and reports on their patients. No information or report should be given without the written consent of the patient, or, if the patient is dead, of the nearest relative or the legal representative. If called as a witness in a criminal case, a practitioner must obey the summons. In a civil case, if served with a summons or subpœna accompanied by conduct money, he must also attend court. If, before attending court, he has not obtained the written consent of his patient or representative to give evidence, he should appeal to the judge, who will direct him to answer questions only if he considers this necessary in the interests of justice.

and many will join their thoughts with mine in this tribute."

"Apart from his professional career," writes G. E. D., "Lake was a man of many parts. It was most interesting to hear of his adventures in the Sudan Campaign at the front and at the base in Suakin, where the medical equipment and service was so primitive when compared with modern times. As a fisherman he was supreme—a real master of the gentle art. His knowledge of salmon and trout fishing was profound and his studies on the grayling bore fruit in a most interesting book. He was in every sense a gourmet and an epicure in his knowledge of good food and wines. A brilliant conversationalist, he possessed a keen sense of humour—though he was frank and outspoken to all with whom he came in contact, he was never influenced by any motive except that of doing his duty in giving his counsel and advice. He had no use for 'isms' and State control. He deplored class hatred which he both disliked and feared. All who had his friendship will miss him greatly."

By his marriage to Miss Mildred Pelly he had a daughter. In 1918 he married, as his second wife, Ellen, daughter of Mr. George Sapsworth.

Appointments

ASHBY, M. G. C., M.A., B.M. Oxfd, M.R.C.P.: physician, Archway group of hospitals.

Births, Marriages, and Deaths

BIRTHS

BROOKS.—On Oct. 30, at Oxford, the wife of Mr. Donal Brooks, F.R.C.S.I.—a daughter.
DENT.—On Oct. 22, the wife of Dr. C. E. Dent—a daughter.
FORRESTER.—On Nov. 2, at Llanelly, Carmarthenshire, the wife of Dr. G. S. Forrester—a son.
GRYLLS.—On Nov. 2, in London, the wife of Dr. Henry Grylls—a son.
MARSH.—On Nov. 1, in Philadelphia, the wife of Dr. Kenneth Marsh—a daughter.
SCOTT.—On Oct. 31, in London, the wife of Dr. Leslie Scott—a son.
STOKER.—On Oct. 24, at Cambridge, the wife of Dr. M. G. P. Stoker—a son.

MARRIAGES

ATTWOOD—BROWN.—On Oct. 29, in Manchester, Roy Wilton Attwood, M.R.C.S., to Margaret Kathleen Brown.
UNWIN—SLACK.—On Oct. 31, at Bishopsteignton, Peter Unwin, M.C., M.B., to Marjorie Hume Slack.
WATSON—LOWIS.—On Oct. 10, at Dunleer, co. Louth, Eire, John Ernest Watson, M.B., to Margaret Sarah Lowis.

DEATHS

DAVIS.—On Nov. 5, the Rev. George Brocklesby Davis, M.A., M.D. Camb., aged 76.
EASON.—On Nov. 2, in London, Herbert Lightfoot Eason, KT., C.B., C.M.G., M.D., M.S. Lond., F.R.C.S., aged 75.
FAIRBAIRN.—On Oct. 31, in London, Donald Charles Fairbairn, M.C., M.B. Lond.
LAKE.—On Nov. 1, at Bristol, Richard Lake, F.R.C.S., aged 87.
MUIR.—On Oct. 29, at Box, Glos, Joseph Corbett Muir, M.D. Camb.
NIXON.—On Nov. 4, at Bath, John Hobart Nixon, M.D. Lond.
PRIDMORE.—On Nov. 3, at Chale, Isle of Wight, John Walter Pridmore, M.R.C.S., aged 79.
SHIPTON.—On Oct. 31, at Milford-on-Sea, Hants, William Shipton, B.A., M.D. Camb.

Notes and News

VACANCIES ON MANAGEMENT CO

AT the end of next March the term of office of third of the members of all hospital management c will expire; and these members will be eligible ment for a further term of three years. In a cir regional boards, the Ministry of Health urges that, as the committees were constituted, full consultation precede the filling of the vacancies, with a view to "a balanced membership including the appropriate typ experience and reflecting the interests of the be served"; and among the bodies to be consulted committee itself, every local health authority and exec council served by the committee, and the senior med and dental staff of each of the hospitals concerned Minister, while he sees no objection, especially on this occasion when the term of office has been short, to reappointment of a reasonable proportion of the members, considers "that Boards should not lose the advantage, on each occasion, of introducing at some new element into the membership, e.g. from Committees or from the local community. The annual rence of vacancies also offers an opportunity for rev the present composition of Committees in the light of e ence and adjusting it where desirable." In this conn the circular draws attention to the following points:

1. The proportion of professional members should not be "The Committee must essentially be and remain a group of the local community . . . and any impl is a body more likely to be concerned ff than those of the community woul

l members should normally be derive om names proposed by the hospital and not from other sources.

3. In general, officers of committees should not be appoint members of them.

4. While it may be convenient to boards to have a few of very exceptionally memb

ly iden

5. In order that the local comm it controls, regional b with the committee and the hospitals it controls, regional b should consider whether any additional organisations repr the consumer interest could usefully be consulted. It is o boards to appoint members whose names have not been put them through the machinery of consultation, but who are individually to be capable of contributing valuably to the serv

As regards casual vacancies, boards should use discretion on the question of consultation; the Act req them only to consult the committee itself.

HARVEY'S PORTRAITS

GREAT men of our day can never become as legenda their forerunners. Posterity will see for themselves cigar of a Churchill, the beard of a Shaw; and will these significant figures in action on the screen, and their voices on well-preserved sound-tracks. They will lose forever the sort of pleasure Mr. Geoffrey Keynes enj in his pursuit of William Harvey's dead face. He told story in the Thomas Vicary lecture, 1948, and it has been published, with beautifully reproduced pictures, by Royal College of Surgeons.[1] Harvey, with his cold eye, his broad high forehead, and his complexion colour of wainscot," has been much painted, but not it seems, from the life. A good market for his pictures am doctors has ensured that the pictures should always forthcoming. Mr. Keynes is severe about their origins will allow only two portraits and one bust to be genu lifelike. These are *the state* portrait in the Royal Co of Physicians, the portrait in the Hunterian *collection* of University of Glasgow, and the bust in Hemel Hemps church. He argues that the Ditchingham Hall port which shows Harvey in three-quarter length with a fringed handkerchief in his hand, may be a posthumo production, because it has lost that lift of the eyebrow wh gives a characteristic tartness and decision to the face the two authentic portraits. The average, less inform clinician, however, would be inclined to say the arre had mellowed with age; for the Harvey of the Ditching portrait—and also of the portrait in Kent and Canter Hospital, and of an etching attributed to Richard Gay —looks older (and iller) by a good ten years than the Hu

HOGENESIS OF ATHEROSCLEROSIS

J. B. DUGUID
M.D. Aberd.
ESSOR OF PATHOLOGY IN THE UNIVERSITY OF DURHAM

; long-accepted interpretation of atherosclerosis,
eroma as it used to be called, may seem satisfactory
he histological point of view, but it is not altogether
ordance with the principles of vascular physiology.
sease which so commonly affects the aorta, coronary,
al, and other medium-sized arteries, and which
pathologist constitutes one of the most familiar
nan lesions, consists, according to modern teaching,
fatty degeneration with a fibrous overgrowth of
tima. Histologically there is undoubtedly a fibrous
ning of that coat, but there is something about the
ning which makes the overgrowth interpretation
lt to accept. It is the narrowing which is so
only produced in medium-sized vessels such as the
ry arteries. When the functional activity of the
il system is taken into account it would appear
a fibrous overgrowth of the intima must cause
ing of an artery rather than narrowing.

get a true conception of the nature of arterial
e one must take functional activity into account
onsider what effects the various lesions will have
ie pulse movements of expansion and recoil.
ally, when the internal pressure in an artery
n systole its walls yield and expand, but by virtue
eir elastic recoil they are able to return to their
al dimensions when the pulse wave passes. It
us their elasticity which allows them to be
tedly expanded without becoming permanently
ded. In reference to these activities it is important
te that while the expansion is a movement imposed
e arteries by the blood-pressure, the recoil is a
on of their own elasticity; and therefore anything
reduces this property will diminish their powers of
, or, in other words, cause them to remain more
s dilated. Fibrous overgrowths, it will be agreed,
reduce their elasticity; and so, if atherosclerosis
of such a nature, it should cause the arteries to be
d rather than narrowed.

e problem is usually viewed in a somewhat different
m, it being suggested that a fibrous overgrowth by
ing an artery will help it to resist expansion. This,
ver, ignores the fact that the arteries during life
onstantly under the influence of the blood-pressure,
at any tissue growing in their walls must as it
accommodate itself to the movements imposed
at force. A fibrous overgrowth would from its
tion have to conform to the normal expansion of
essel at each systole or be torn asunder as it formed,
it therefore would not be likely to offer much
ance to that movement. It would, on the other
, by reducing the elasticity of the vessel, be likely
terfere with the recoil, and, were it to increase
initely, it would ultimately tend to fix the vessel
y in the expanded position.

om another point of view it has been contended that
rous growth may constrict an artery by a kind of
ricial contraction; but this again is contrary to
iological principles. In constricting an artery in
way the fibrous tissue would be taking the whole
ht of the pulsating blood-pressure on itself, and,
we believe that it is only by virtue of their elasticity
the arteries are able to do this without becoming
anently distended, we must assume that the
ively inelastic fibrous tissue would gradually give
r the strain. Moreover, we have the example of
rysms to show that this is a justifiable assumption.
n theoretical grounds, therefore, it is hard to see
a fibrous overgrowth could have any other effect than to widen the arteries; yet we find that the fibrous thickenings in atherosclerosis commonly narrow them almost to the point of occlusion. This apparently conflicting observation has led to the suspicion that something must be wrong with the orthodox interpretation of atherosclerosis, and that some other explanation more in accord with physiological principles is to be sought. From the study of aortic and coronary disease I am led to believe that it is the overgrowth conception which is wrong, and that the true explanation of intimal thickening is to be found in the pathology of arterial thrombosis.

THE THROMBOSIS HYPOTHESIS

In two recent publications (1946, 1948) I have shown that lesions morphologically identical with atherosclerosis can be produced by the organisation of arterial thrombi. In these publications the process was illustrated by photomicrographs, but for the present purpose it can perhaps be more simply explained by diagrams. When a thrombus forms in a coronary artery for example, it may first occlude the lumen (fig. 1), but if the individual survives it will tend to retract so that a channel is formed through which the circulation is partly restored (fig. 2). Soon the channel becomes lined with endothelium and a new lumen is thus formed, with the thrombus now lying external to it and forming as it were a part of the vessel wall (fig. 3). Organisation then follows, the subendothelial layer of fibrin on the free surface of the thrombus (fig. 3a) being transformed into fibrous tissue by what appears to be a direct metamorphosis, while around the attached surface of the thrombus (fig. 3b) a vascular zone of organisation is formed which advances into the mass, converting it into fibrous tissue. Since this new tissue is similar to, and continuous with, that of the original intima, it has the appearance of an intimal overgrowth.

In some instances a complete organisation of the mass is brought about in this way; but more often, before the process has reached the centre, fatty degeneration and sometimes softening take place, and thus the picture of atherosclerosis is produced. While these changes are in progress the new lumen under the influence of the blood-pressure gradually widens, while the thrombus shrinks and becomes moulded to the shape of the vessel wall (fig. 4), so that in the end the mass which once filled the lumen is reduced to a crescentic thickening of the intima.

It is of course obvious that atherosclerotic thickenings do not always begin with total occlusion of the arteries; but in this extreme example lies the key to the problem. The thickenings are not to be regarded as growths in the ordinary sense, nor even as products of the vessel walls, since they are actually derived from the blood. The process is almost the reverse of what has usually been pictured, for instead of there being a gradual encroachment on the lumen by an intimal growth, there is a sudden and total occlusion by a mass of blood which subsequently becomes reduced in size as the circulation is re-established. There is nothing in this interpretation which conflicts with physiological principles, because when a vessel is occluded by a thrombus such principles no longer apply. The blood-pressure is eliminated and movements cease, and it is not until the circulation is re-established that these factors again come into play. They then, as would be expected, lead to a gradual widening of the new lumen; but a long time must presumably elapse before the vessel regains its original internal diameter, and it is not to be wondered that narrowing is a common feature of the lesions.

MURAL THROMBOSIS

Most arterial thrombi do not cause total occlusion of the vessels, but merely form fibrinous deposits on the intimal surface; yet they may have the same effect

University of Cambridge

On Oct. 29 the following degrees were conferred:

M.D.—C. C. Bryson, Harry Harris, W. S. Haynes, M. S. M. Palmer, B. G. Parsons-Smith, R. V. Stone, F. W. Watkyn-Thomas.*

* By proxy.

University of London

Dr. J. H. Sheldon will give a lecture at the London School of Hygiene, Keppel Street, W.C.1, on Thursday, Dec. 1, at 5.30 P.M., on Problems of Old Age.

Royal College of Physicians of London

Prof. Norman Capon will deliver the Charles West lecture on Tuesday, Nov. 22, at 5 P.M., at the college, Pall Mall East, S.W.1. He is to speak on Development and Behaviour in Childhood.

Royal College of Surgeons of England

The college is arranging, jointly with the Institute of Laryngology and Otology, a series of lectures. The first will be given at the college, Lincoln's Inn Fields, London, W.C.2, on Dec. 1, by Prof. Geoffrey Jefferson, F.R.S., who is to speak on Intracranial Abscess. The lecture is open to all doctors.

Royal College of Physicians of Edinburgh

At a meeting of the college held on Nov. 1 with Dr. W. D. D. Small, the president, in the chair, a diploma of fellowship was granted to Dr. J. J. R. Duthie (Edinburgh). Diplomas of membership were also granted to the following:

J. H. Wright, W. H. Jopling, T. S. Row, P. C. Mitchell, R. W. Crocket, R. B. Baird, W. H. Perry, J. E. A. Bartlet, D. A. Gordon, R. F. Maggs, H. N. Singh, P. C. Bhattacharjee, W. D. Munro, B. Mukharji, G. I. Robertson, W. J. Weston, M. W. M. Hadley M. J. Murray, K. S. Millingen, J. H. Phowalla, K. R. Keay, D. F Gibbs, A. M. Rudolph, Mary D. Smith.

Royal College of Physicians of Ireland

On Nov. 4 the following were admitted to the membership:

W. G. Keane, D. J. O'Callaghan, I. B. Patwari, O. P. D. Ryan.

Middlesex County Medical Society

A meeting of this society will be held at Clare Hall Hospital, South Mimms, Barnet, on Wednesday, Nov. 16, at 3 P.M.

Oxford Regional Hospital Board

Dr. J. O. F. Davies, deputy senior administrative medical officer to the North West Metropolitan regional hospital board, has been appointed senior administrative medical officer to the Oxford regional hospital board in succession to the late Dr. G. C. Williams.

Long-term Medical Certificates

The National Insurance Advisory Committee have approved the draft regulations extending the maximum intervals at which medical certificates may be given in prolonged illness from 8 weeks to 13 weeks, even though the patient is seen by the doctor at more frequent intervals. These facilities have been made available by provisional regulations since Aug. 4 last (*Lancet*, Aug. 6, p. 262), but it is thought that not all doctors are yet fully aware of them, possibly because of a mistaken impression that certificates for 13 weeks cannot be given until new forms have been issued. The ordinary forms Med. 3 should be used for 13 week-certificates for the time being.

British Standards

The British Standards *Institution* has published the first issue of a sectional list of British standards relating to hospital equipment (P.D. 960). Copies may be had from the sales department, 24, Victoria Street, London, S.W.1.

The new standard for stretchers, stretcher-carriers, and hospital trolleys (B.S. *896/1949*) is a revision of a war emergency standard, published in 1940. The revised standard provides that all ambulances shall accommodate standard 7 ft. 9 in. stretchers; but this requirement need not interfere with the use of non-standard 6 ft. stretchers for special requirements. The specifications for stretchers conform with the recommendations in the manual of the International Red Cross. Preference is expressed for securing stretchers in ambulances by straps riveted to the stretcher-carriers, rather than by special locking devices. Copies of the standard (price 1*s.* 6*d.*) may be had from the sales department.

er dealing with the inflammatory lesions of the es, Rokitansky refers to an

> *essive deposition of the lining membrane of the vessels.* . . . highly developed form of this affection, we find the surface of a large artery, as the aorta, covered with a n substance spread over it at separate points, or in large es, and forming a stratum varying in thickness, by the inner surface of the vessel is commonly rendered n. . . . It varies in thickness . . . and extends in extreme over the whole trunk and main branches of the aorta, ating the entire arterial system.
>
> deposition is generally the thickest directly over the m of a trunk, or at the bifurcation of a vessel. At points the deposit is frequently so thick, that the is of the divergent vessels are much contracted, and wholly closed. . . .
>
> its commencement, this deposition cannot be detected nt a previous familiarity with its appearance. It is a delicate, soft, succulent membrane, exhibiting a us transparency. . . .
>
> deposition continuously increases in thickness by the on of new strata, and thus gradually passes from the ion of transparency and succulence, characteristic ent formation, to that state in which it appears opaque, bling coagulated albumen, and finally presents a ligaous appearance, having a dull, wrinkled surface. . . .
>
> *atheromatous process* consists in the metamorphosis tegration) of the deposit, into a pulpy mass, compared e French to a purée of peas, consisting of a large number stals of cholesterin, fatty globules, and of molecules iting various degrees of consistence, from coarseness to ne fineness, and consisting of albumen and calcareous

kitansky summarises his view as follows :

> *deposit cannot be regarded as a product (exudation) inflammation in the arteries. . . . The deposit is an endos product derived from the blood, and for the most part the fibrin of the arterial blood. Its formation demonstrates re-existence of a peculiar crasis of the blood,* which is sically *arterial*, although at the present time we are y ignorant of the character of the peculiarity on which pends.

okitansky's views were vigorously opposed by low who regarded atheroma as an inflammatory ess, and the thickening as the product of a reactive feration on the part of the intimal connectivee cells. Virchow's inflammatory notion was soon doned, but his conception of a cellular proliferation continued to influence our views to this day, and rdingly the fibrous thickenings have been almost ersally regarded as overgrowths. Some of the early orities considered that they were designed to reinforce s of weakening in the vessel walls, whereas the more nt observers, with experimental cholesterol sclerosis ind, have been inclined to view them as proliferative tions to the presence of fatty changes. Thus, while e has been almost constant speculation as to the ible causes of overgrowth, the fundamental question ther or not the thickenings are in fact overgrowths hardly been considered.

ew would claim that the work of the last century, d on the overgrowth hypothesis, has led to a satisory explanation of the problem, and we should well to re-examine the grounds on which Virchow able so effectively to discredit Rokitansky's views these have been all but forgotten. They were lained at great length by Virchow (1856) in a paper ch when analysed amounts to little or nothing more n the argument that the lesions, being subendothelial osition, could not be surface deposits. This we now w does not follow, since surface deposits in arteries urally become covered with endothelium. We know that his summary dismissal of the thrombosis othesis was unjustified, because mural deposits loubtedly do occur and in due course develop into ous thickenings. On that score alone, therefore, kitansky's views deserve some further consideration ; when the theoretical points outlined at the beginning of this communication are taken into account their claims become stronger. Fibrous overgrowths of the intima would not be likely to narrow the arteries in the way atherosclerosis does, whereas mural thrombi could hardly do otherwise. Obviously we must no longer take it for granted that all the tissues which lie under the endothelium of the arteries are necessarily intimal in origin, or that the changes we find in them must have arisen within that coat. We now know that the incorporation of surface deposits from the blood is a natural process in the arterial walls,* and we must assume that, if mural deposits in arteries are common the intimal thickenings which result from them must also be common. It remains for future workers to decide which intimal thickenings are the result of surface deposits and which are not.

The introduction of the thrombosis hypothesis, it must be admitted, leaves the problem of the significance of fatty changes in atherosclerosis still unsolved. Mural thrombi, including even the fibrinous vegetations in endocarditis, commonly develop lipoid changes in time, and there seems little doubt that the lipoid substances are products of the thrombi. But it is not to be supposed that all such substances appearing in arterial diseases are derived from this source. Those which are produced in the rabbit's aorta by the administration of cholesterol are presumably the result of a metabolic disturbance, as are probably also those which appear in the human aorta in the condition known as superficial fatty streaking. Here the problem becomes more complex because there are clear indications that fatty changes may sometimes be the cause as well as the result of mural thrombosis. There is little doubt, for instance, that it is the fatty changes and softening of the intima which lead to the atheromatous ulcers with which mural thrombi in the aorta are commonly associated, and it seems likely that the same sequence on a smaller scale may figure in relation to superficial fatty streaking. In that condition fat-laden cells collect under the endothelium and cause it to bulge in a way that would render it liable to rupture, and it is perhaps significant that it is in those places where superficial fatty streaking is common—namely, near the origins of the intercostal branches—that the finer fibrinous encrustations are most readily found. Again it would probably be wrong to suppose that all surface deposits depend on some lesion of the underlying intima, for there is reason to believe that vascular thrombosis is sometimes a general rather than a local condition, occurring in many parts of the vascular system at one time, irrespective of the state of the vessel walls.

CONCLUSION

The thrombosis hypothesis opens a new approach to the problem of arterial disease. If we admit that intimal thickenings may not be overgrowths of the arterial walls, but products of the blood, then in seeking to discover their cause we must no longer confine our attention to the identification of the agents which act on the vessel walls, but must also consider the factors which govern fibrin formation in the circulating blood. In late years evidence has been accumulating that there are certain pathological conditions in which the tendency to thrombosis is unduly increased, and it may be that it is in the frequent recurrence of such conditions that the chief dangers to vascular efficiency lie.

as those which do. Mural thrombi in arteries are commoner than is generally supposed, and are extremely variable, ranging from the familiar red masses which develop in the aorta in relation to atherosclerotic ulcers down to microscopically thin fibrinous incrustations, the existence of which is not generally realised. Such deposits become organised and form fibrous thickenings, and when large they may narrow the vessels considerably. Their organisation is essentially the same as that already described, but the process involved depends to some extent on the thickness of the deposit. The thrombus first becomes covered with endothelium so that it is incorporated in the intima, and if it is thin it may then undergo a direct transformation, the fibrin, which forms a shallow layer under the endothelium, becoming condensed and hyaline in appearance and later assuming the staining characters of collagen so that a new fibrous lamina is added to the vessel wall. The intermediate hyaline stage of this process is often very striking, and its appearance and position may give the impression of a hyaline or fibrinoid degeneration of the collagenous ground substance of the intima itself. If, on the other hand, the mural thrombus is large and thick, its conversion into fibrous tissue is more complicated. While the subendothelial layers undergo a direct transformation like that just described, the deeper ones may become vascularised and go through the same process of organisation as is seen in a venous thrombosis or a fibrinous exudate, and there seems little doubt that it is this which gives the appearance often referred to as vascularisation of the intima in atherosclerosis.

In the large deposits fatty changes also appear, chiefly in the deeper zones which are last to become organised, and thus foci of the atheroma are formed. Such foci are not necessarily permanent, however ; for as the organisation advances the lipoid substances are gathered into phagocytic cells and disposed of, while the underlying fibrin is converted into fibrous tissue. Sometimes, in addition to fatty degeneration, softening takes place, and also calcification, with only a relatively limited organisation, and it is in such instances that rupture of the surface occurs with the formation of atheromatous ulcers.

When mural deposits are newly formed they are usually loose in texture, bulky, and ragged ; but they soon become smoothed out and compressed, and as they are converted into fibrous tissue they grow more compact so that quite large deposits may in the end be reduced to comparatively inconspicuous fibrous thickenings. Represented in this way the lesions would appear to be regressive, whereas atherosclerosis as we know it is a progressive disease which increases with age. Its progressive nature may be explained by the fact that mural thrombosis is a recurring condition. In the aorta and coronary arteries multiple deposits of fibrin of different ages and in different stages of organisation are commonly found, one on top of the other. Thus the thickenings which appear in the arteries of old people are often the cumulative effects of recurring thrombosis ; and the individual deposits, though may be small, may nevertheless if often repeated about progressive thickenings which result in e narrowing of the vessels. It should be added that process of organisation not only fibrous but also tissue is formed. With laying down of suc deposits the thickenings become stratified, and be the fibrous strata elastic laminæ develop, so th appearance suggesting a reduplication of the system of the vessel is produced. Much of the comp of the histological picture of atherosclerosis m accounted for by these multiple deposits and b remarkable variety of appearances produced in organisation. The so-called hyaline or fibrinoid deg tion, the vascularisation with occasional extravas of blood, and the fatty changes, which have long regarded as characteristic of atherosclerosis a common features of mural thrombi.

EXPERIMENTAL CONFIRMATION

It is not difficult to show experimentally that thrombi are converted into fibrous thickenings vessel walls. Arterial thrombi can be produced by simple procedures as puncturing the central arte a rabbit's ear, or inserting threads into the femo carotid arteries of dogs, and they quickly become co with endothelium and organised so as to form in thickenings. They thus bear out the thrombosis thesis ; but such experiments are crude as com with those devised by Harrison (1948) in which divided fragments of fibrin clot were injected int veins of rabbits so as to produce emboli in the pulm arteries. The emboli adhered to the walls of the ve became organised, and in three or four weeks fo thickenings comparable with those seen in h pulmonary hypertension. Moreover, it was noticed the thickenings found in the animals which were all to survive for some months had shrunk and were conspicuous than those in the animals killed early i experiments.

DISCUSSION

The existence of a process in which arterial thr are converted into fibrous thickenings has long recognised in thrombangiitis obliterans and al aneurysms, but that the same process may be conce in the pathogenesis of atherosclerosis has not gene been taken into consideration. Yet even in conne with atherosclerosis the thrombosis hypothesis i new conception. A century ago Rokitansky desc atheroma as a deposit on the surface of the vessel fibrinous material derived from the blood, with a f metamorphosis occurring in the deposit. A few sele passages from his *Manual of Pathological Anatomy*, tr lated by George E. Day (1852), will serve to show completely his views anticipated those I have now forward.

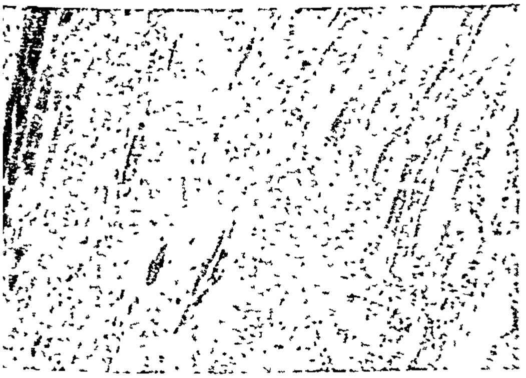
ation and granulation tissue were present at the ary of the lesion. Some of the arterioles present in the showed endarteritis, with some hyaline change in lia (fig. 2).

iography was done through the femoral artery in the part of Hunter's canal, and all the tibial vessels filled y; this also was not done until eight weeks after the nptoms.

ess.—No recovery in power of the tibialis anterior extensor hallucis longus muscles occurred, but the r digitorum longus and brevis both returned to and the area of sensory loss gradually diminished n the patient's discharge fourteen weeks after his nptoms, sensation was normal. In spite of the complete of recovery in the tibialis anterior and extensor longus there was only minimal disability, since the s held more or less horizontal to the ground owing to a ture of these two muscles.

r-up.—The patient was seen again six months after ge, when there was no voluntary or reflex contraction two affected muscles, which were still silent on nyography.

8.—A sergeant, aged 29. He was wounded in action . Europe on Aug. 14, 1944, sustaining a bullet wound ght shoulder with a compound fracture of the humerus ell-splinter wounds of the left chest wall and arm, er involving the brachial artery and median and ulnar The right leg was uninjured. At a field transfusion was given a pint of blood into the right internal ous vein. Next day the wounds in the upper limbs erated on; the left brachial artery was found to be in Two days after injury there was "swelling of the kle, with inflammation of the dorsum of foot and along terior border of the tibia." In view of the severity wounds it is not surprising that little attention seems been paid to the right leg. On Aug. 30, 1944, a right op was recorded and a back-splint applied to correct The patient stated that his right leg "became septic" he blood-transfusion and was treated with 'Antitine.' Three days later he had a severe burning pain foot and could not raise it. He was not aware of any ess of the foot. The pain and inflammation subsided lly in about a fortnight, but the foot-drop remained.



Biopsy specimen (case 2) showing necrotic muscle and granulation tissue. (×50.)

xamination three months after injury the findings in ht leg were as follows. There were two small wellscars over the line of the internal saphenous vein. nt degree of foot-drop was present. There was no nt wasting of the muscles—if anything, the anterior muscles appeared to be more prominent on that side, easurement did not reveal any increase in girth. The r tibial muscles felt hard but were not tender; the uscles were quite soft. Tibialis anterior, extensor um longus, and extensor hallucis longus were paralysed; vas slight extension of the two outer toes by the extensor um brevis. Power in all the other muscles of the leg, ng the peronei, was normal. There was no objective jective disturbance of sensation. The dorsalis pedis sterior tibial pulses were of good volume, and the skin , skin temperature and nutrition of the right foot were similar to those of the left. Clinically, sweat secretion was normal.

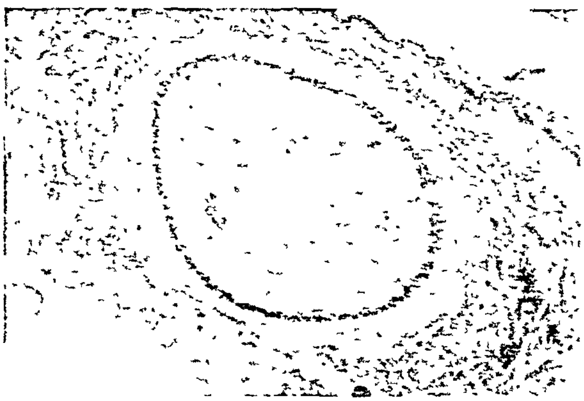


Fig. 4—Biopsy specimen (case 8) showing healthy blood-vessel in infarcted tibialis anterior muscle.

Electrical Reactions.—None of the muscles of the anterior tibial compartment responded to faradism or galvanism. The peronei reacted normally, as also did the extensor digitorum brevis.

Electromyography.—Silence was recorded from all the muscles of the anterior tibial group.

Reflex Vasodilatation Test.—A normal response was obtained from both feet.

Muscle biopsy was done four months after the onset of symptoms. Macroscopically, the tibialis anterior was grey, firm, and avascular. Microscopically, there was massive ischæmic necrosis of representative sections from all the tissues supplied. In one section replacement fibrosis of some duration bordered the anuclear striated dead muscle-fibres. The arterioles and venules present had healthy walls and in some places contained the elements of fluid blood (fig. 4).

Follow-up.—Fifty-three months after the onset of symptoms there was no recovery in any of the muscles of the anterior tibial group. There was a contracture of the long extensor tendons of the toes, but a check-iron was still worn to control a slight degree of foot-drop.

CLINICAL FEATURES

History

As regards onset, the cases can be divided into two groups. Group 1 includes cases 1–6 and 9. In all of these there was a history of activity involving strenuous use of the muscles of the leg either before or at the time of the onset of symptoms. In cases 1 and 3–6 the initial symptom was pain in the leg while playing football, and in all these cases the pain was first noted when kicking. In case 9 pain was first noted at night while the patient was in bed, but he had played football that afternoon. In all cases in this group pain was followed by swelling over the anterior tibial compartment, the classical signs of inflammation, and, later, inability to dorsiflex the foot and toes. Group 2 consists of cases 7 and 8, in which injuries to parts of the body other than the affected limb caused oligæmic shock, for which the patients were transfused into the veins of the leg. Within a short time of the transfusion both patients complained of pain in the front of the leg into which the transfusion had been given, and were later found to have paralysis of the anterior tibial muscles. We regard these two cases as most important from the point of view of the pathogenesis of the syndrome.

Age

The average age of the patients was 25, with extremes of 18 and 40. Except for case 3 they were previously fit members of H.M. Forces.

Limb Affected

In group 1 the right leg was involved in 5 cases and the left leg in 2 cases. Unfortunately, data are not avail-

IN the last five years there have been several accounts of a peculiar condition, apparently not described before, affecting the muscles of the anterior tibial compartment of the leg.

In a paper on soft-tissue complications of fractures of the leg Sirbu et al. (1944) described 2 cases of localised gangrene of the anterior tibial muscles not associated with fracture. In the first of these, on the fifth day after the repair of a small muscle hernia through the anterior crural fascia, fever and signs of inflammation developed; the sutures in the skin and fascia were removed to reveal a greyish-white gangrene of the tibialis anterior muscle, the entire belly of which was excised. Their second case was in a soldier, aged 38, who developed severe pain in the front of both legs after marching. He was seen on the fourth day after the onset of this symptom, when the fronts of his legs were swollen and red and he could not extend his feet or toes. Exploration of the anterior tibial compartments in this case also revealed avascular greyish-white muscles which on histological examination were necrotic.

Horn (1945) described 2 cases of acute ischæmia of the anterior tibial muscles and long extensor muscles of the toes. Both patients were young healthy soldiers who developed severe pain along the fronts of the legs while marching. This was followed by swelling, redness, and glossiness of the skin over the anterior tibial compartment and by paralysis of the tibialis anterior muscle and the extensors of the toes. Phalen (1948) included among 4 cases of ischæmic necrosis of the anterior tibial muscles that of a young man who, after a half-mile walk, developed painful swelling of the pretibial muscles. At operation the affected muscles were soft, friable, and reddish-grey. Pearson et al. (1948) have reported the same condition in a young Greek in whom symptoms developed in both legs after broad-jumping on a concrete pavement.

These reports are all from America, but in this country Hughes (1948) has published 3 cases of "ischæmic necrosis of the anterior tibial muscles due to fatigue." Two of his patients were fit Servicemen who developed symptoms after playing football. The third was a youth, aged 19, whose symptoms developed in association with a systemic febrile illness which may have been periarteritis nodosa.

While working in three widely separated areas of this country we have seen 9 cases, 2 of which we report in detail, all of them being summarised in tables I–IV.

ILLUSTRATIVE CASE-RECORDS

Case 1.—A signalman, aged 20. Seven weeks before admission he played three games of competition football on three successive days under muddy conditions with a sodden and heavy ball. On the third day he found that on running and kicking he experienced pain down the front of the right leg. He carried on through the first half of the match, but later the pain became unbearable, and he limped off the field. He rested for 5 minutes and then tried to play again. After once more kicking the ball he felt the pain come on again severely, and found he had suddenly developed on the front of his leg an oval swelling about 3 in. by 2 in. two-thirds of the way up the shin. This swelling was tender, warm, and throbbing, and though it was so localised certain that he had not been kicked on the leg game. He immediately stopped playing and rested, off to his billet; the throbbing pain continued and ke awake part of the night. Next day he limped round the and on the following night the pain was worse. On the morning after the onset the swelling was surrounded area of redness about 6 × 3 in. The patient was bed and treated as a case of cellulitis of leg, with sy penicillin. He had a fever of 99–100°F for five days, and the pain, redness, and swelling persisted for one more day before it disappeared. He then tried his foot for the first time and found he could not dorsiflex it or straighten his toes. A week later some movement returned to his toes, and then his condition remained stationary until he was admitted to hospital seven weeks after the onset. His past history showed that on route marches he had had pain in the front of both legs, and, even before joining the Army at the age of 17, he had had pain in his legs after severe exertion.

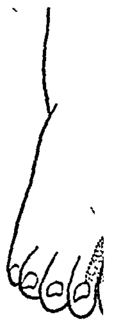

Fig. 1—Area of loss (case

Examination showed a diffuse woody indurated swelling of the right anterior tibial region, extending from 2 in. below the lower of the patella to 3 in. above the malleoli, warmer than the other side, painless, and not tender. patient could not dorsiflex his right foot or rig toe at all, but there was only a minimal degree of foo since the tendons of the anterior tibial and extensor h longus muscles were standing out and easily palpable i of the ankle-joint, suggesting a persistent spasm or contr of these muscles. In addition there was some weak dorsiflexion of the four lateral toes, and the extensor dig brevis muscle was not contracting. An area of senso to cotton-wool touches and of blunting to pinprick ex from the dorsum of the big toe round to the dorsum second toe, including the skin fold between the two The dorsalis pedis and posterior tibial arteris were pu normally to touch; oscillometry was not done.

Electrical Reactions.—Normal responses were obtai the extensor digitorum longus and brevis and pe longus and brevis muscles. There was no response to f or galvanic stimulation in the tibialis anterior and the ex hallucis longus muscles.

Electromyography.—There was complete silence i tibialis anterior and extensor hallucis longus muscles, normal motor unit action potentials elsewhere in the le

Muscle biopsy was done eight weeks after the on symptoms, the tibialis anterior muscle being incised. scopically it was clearly ischæmic, especially in the d areas, where it was yellow and appeared entirely ava In its more superficial part there was some bleedi incision, and these fibres appeared normal. Microscop the biopsy specimen, though still retaining the outline muscle fibrils, showed complete loss of nuclei and all detail. The small vessels in between the fibrils were eng with blood. The appearance was one of infarction.

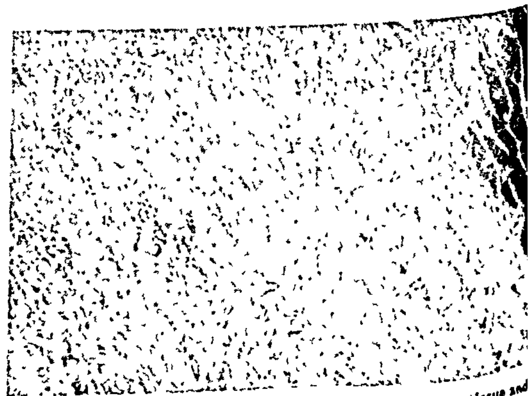

Fig. 2—Biopsy specimen (case 1) showing dense fibrous tissue and of necrotic muscle. (× 50.)

ed the appearance of the muscle as normal (note is is a case in which the extensor digitorum longus t paralysed).

microscopical findings in the muscles are illustrated 2–4, and the salient features of the pathological are given in table IV. The findings may be rised as follows: (1) except in case 4, the overture was that of massive ischæmic necrosis of (infarction), with replacement fibrosis taking rom the periphery; (2) evidence of recent or old rhage within the muscles was observed in some cases; and (3) the blood-vessels in the muscles ed healthy or else showed changes which were tible with the fact that the muscle which they pplying had been dead for some weeks.

ress.—Of the 9 patients 2 were not followed after lischarge from hospital. Three were kept under ation for less than twelve months after the onset ir symptoms. This period is probably too short ble progress to be accurately assessed with a lesion nature, but nevertheless some interesting and, we e, significant factors emerge from these 3 cases. was recovery of sensation and activity in the or digitorum brevis in cases 1 and 2 at fourteen and three months respectively. In case 4 both the s anterior and the extensor digitorum longus showed recovery at six months. The other 4 cases have followed for long periods—case 5 for fifty-four s, case 6 for fifty-six months, case 7 for forty-nonths, and case 8 for fifty-three months. In all cases the degree of recovery in the anterior tibial es was minimal. All still required some form of atus to control the foot-drop, and in 2 of the cases l 8) contractures of the long extensor muscles of the ad caused trouble.

TABLE II—MUSCLES INVOLVED

eronei		Tibialis anterior			Extensor digitorum longus			Extensor hallucis longus			Extensor digitorum brevis

V, voluntary contraction (M.R.C. notation).

F, faradic response; G, galvanic response: + = normal. ± = weak response. — = absent response.

N.R., no record.

Electrical reactions unsatisfactory because of œdema.

Lesion
